It must be understood that the acceptance by the British Medical Association of an Advertisement does not imply a recommendation, and that no responsibility is accepted with regard to the accuracy of the statements therein contained.

Scotland, Northumberland, and Durham

THROUGHOUT the Northern area the announcement, made in last week's issue, regarding the establishment of a Scottish Office of the Medical Insurance Agency in Edinburgh has aroused great interest amongst readers of the Journal.

Now is the time to consider whether you are adequately covered against everyday risks and if policies you at present hold are satisfactory. Before renewing such policies it will be wise in any case to take advantage of the wide experience of the Agency's expert staff, who will be pleased to submit a considered opinion. The Medical Insurance Agency is completely independent and therefore free to advise the purchase of policies from those Offices offering the best terms to medical men. Motor policies have been arranged by the Agency at especially favourable rates and upon advantageous conditions.

Remember!

IN any and every Insurance question the Scottish Office is at your service and there is no charge to you for the protection which the Agency ensures.

Write, therefore, stating your needs to:

THE MEDICAL INSURANCE AGENCY LTD.

(SCOTTISH OFFICE).

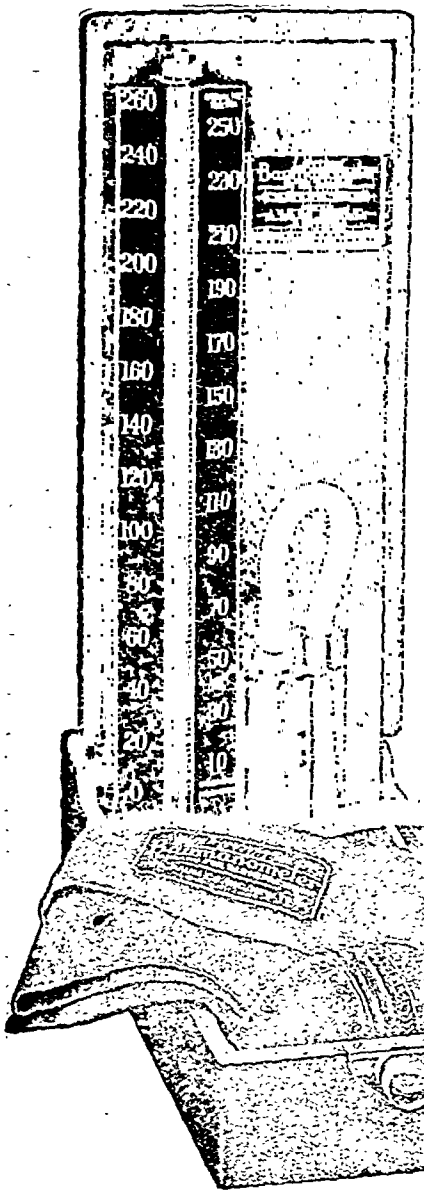
The *Lifetime* GUARANTEE

—*its TRUE significance*



The Baumanometer is the only instrument in all of the world that is GUARANTEED against glass breakage. The *reason* for this guarantee embraces certain facts, the more important of which are set forth in the following excerpts from an original scientific article which appeared in the Journal American Medical Association, Nov. 20, 1926, Vol. 87, pp. 1742 and 1743. The instrument referred to, of course, is the new Lifetime Baumanometer.

> A new mercurial sphygmomanometer in which several important and well established objections to this type of bloodpressure instrument have been overcome has been developed recently. Its novel design reduces the possibility of accidental breakage of the glass tube practically to the vanishing point . . . . Several features of the design account for the almost complete elimination of glass breakage. . . . The tube is held in a resilient mounting which permits it to yield considerably to side and end thrusts and thus to withstand, without damage, shocks that would otherwise shatter it. The effectiveness of this unique mounting in absorbing the hardest jolts and jars, and thus protecting the glass tube from breakage, has been demonstrated. A completely assembled instrument was repeatedly dropped in all positions from a height of 4 feet on to a hard floor, without injury to the tube in any instance. . . . . it can easily be imagined what would have been the effect on a cemented or otherwise rigidly mounted tube. . . . . The almost complete elimination of glass breakage, and the simple means for making a repair in the rare case in which breakage does occur, removes a most exasperating difficulty heretofore experienced with mercurial sphygmomanometers. . . .
> The design of the instrument shown (made by the W. A. Baum Company, New York) was developed along the lines of maximum service and convenience to the user, without the sacrifice of simplicity and ruggedness, which experience has shown to be so desirable in instruments of this character.

That is why the Baumanometer is guaranteed against glass breakage; and why no other instrument is so guaranteed at all—much less for the user's *lifetime!*

That is why we can assure you of perfect, uninterrupted bloodpressure service for your lifetime... *You couldn't expect more, —don't be satisfied with less.*

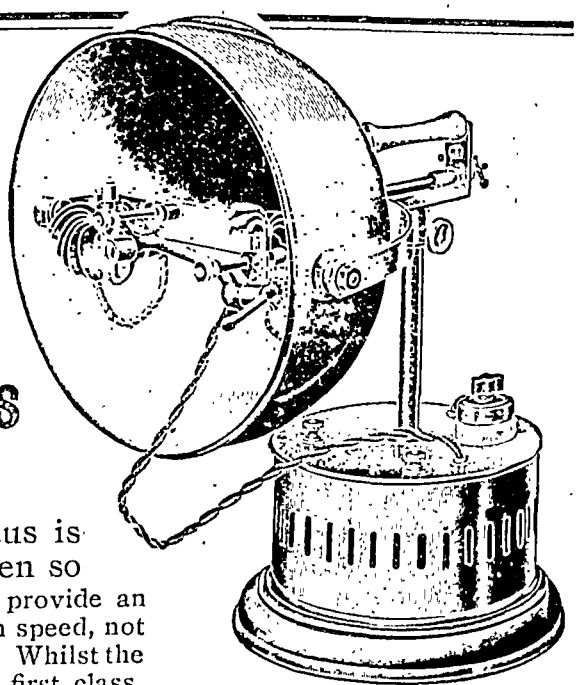
"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.



Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: **30 TREATMENTS 3d.**

Price:
For use on Direct Current ... £12
For use on Alternating Current £18

Relief for Chronic Backache

Through Proper Support

CHRONIC low back pain, physicians agree is, in the majority of cases, due to a lumbosacral or sacro-iliac lesion.

Study of the relationships of the bony structures of the lower back to each other and to the attached ligaments and muscles, has shown how readily trauma may occur.

Heavy lifting or pushing, especially when the torso is bent or twisted, bad posture, difficult childbirth, or any other condition which creates abnormal tension in the muscles or ligaments of the sacro-iliac or lumbosacral regions, may cause low back injury and pain.

Cases so caused can be satisfactorily dealt with by the immobilization of the articulations involved.

After the area of tenderness has been determined, the physician can secure fixation of the lumbar or sacro-iliac joints by the use of a Spencer belt or corset designed with a lumbosacral or sacro-iliac pad which acts as a fulcrum in securing proper adjustment.

With the bony structure held in position, the bruised or strained ligaments are relieved of tension or pressure, and the return to normal condition hastened.

Each Spencer Support is especially designed for the patient who is to wear it. The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of sacro-iliac strain, hernia, enteroptosis, movable kidney, and for maternity wear. We will gladly send you any of them in which you are interested.

Spencer Sacro-iliac Belt

The belt shewn in the illustration is designed from special measurements and figure description for the individual who is to wear it.

Spencer sacro-iliac belts are made for both men and women.

Intestinal Disinfection

HYPERPIESIS

HYPERPIESIS is described as "a malady in which blood pressure rises excessively, a malady having a course of its own and deserving the name of a disease."

A writer in THE LANCET describes cases of this condition, and ascribes its causation to toxic substances of the nature of which he is uncertain, but which he believes to be extra-renal in origin and to be distributed by the blood stream.

It seems highly probable that these substances are the "pressor" substances such as epinephrine, which are developed by putrefactive bacteria in the intestine. Assuming the truth of this likely hypothesis, the treatment in part should obviously consist in adequate intestinal disinfection.

Certain compounds of the coal-tar series, having high germicidal value and little solubility in the alimentary tract, pre-eminently possess this disinfecting power and form the active constituents of Kerol, which may be given in a palatable form by means of keratin-coated capsules which ensure disinfection of the alimentary tract without deleterious effect.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

INSULIN 'A.B.'

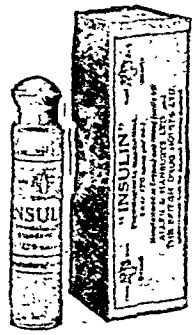
TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/- each

CAPROKOL

(Hexyl-resorcinol B.D.H.)

For the complete disinfection of the urinary tract Caprokol is the drug of choice.

Pain, frequency and the allied unpleasant symptoms characteristic of diseases of the urinary system are relieved immediately by Caprokol treatment.

The physician who prescribes Caprokol witnesses a rapid improvement in the general health of his patient as a result of the comfort experienced by night as well as by day. The necessity for frequent micturition ceases, hours of continuous sleep follow, the appetite increases; most important of all, however, is the continuous germicidal action of the drug.

A SPECIFIC FOOD FOR NERVE AND BRAIN CELLS

WHEN nerve and brain cells become impaired through the slowing-down of active and healthy cell-metabolism normal conditions can quickly be restored by the administration of Lipoids possessing a definite organ specificity.

In "NEW-PROMONTA" medical men have at their disposal an organic food rich in Nerve Lipoids in Phosphatides and Cholesterols, which by a special process are preserved in the identical quantities and conditions in which they exist in the living cells. "NEW-PROMONTA" assists metabolism and restores debilitated cells.

"NEW-PROMONTA" has other valuable constituents—Lime, Hæmoglobin, Iron, Albumins, and the Vitamins A, B, D, and E—which make it a very excellent tonic food and body builder in the treatment of malnutrition, debility, and all nervous disorders.

TO TEST "NEW-PROMONTA."

A trial supply of "NEW-PROMONTA" will be sent post free to any Doctor, Clinic, or Hospital on application.

"NEW-PROMONTA" in Tablet form is supplied in handy boxes containing 54 tablets at 3/6. Each box includes a metal container for the pocket which holds a day's supply. "NEW-PROMONTA" in powder form is supplied in sealed air-tight boxes of ¼-lb. at 3/-, and ½-lb. at 5/6.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7

ALOCOL

Colloidal Hydroxide of Aluminium

Internal and External Germicide. **T.C.P.** **(Trichlorophenylmethyliodosalicyl)**

T.C.P. is a synthetic chemical of the "Organopolyhalogens" class. It is not caustic and it is a perfect disinfectant of the alimentary tract. It acts as a chlorinating agent of the bacterial proteins and as an oxidising agent of bacterial toxins.

EXTERNALLY T.C.P. suppresses inflammation, prevents infection, promotes smooth granulation and rapid healing. Every form sepsis yields readily to **T.C.P.**

.....M.B. (London), some time Deputy Commissioner of Medical Services, London Region, Ministry of Pensions; lately Medical Superintendent, Ministry of Pensions Hospital, ... , reports:—

"The Applications of T.C.P. and its Indications in Medical and Surgical Practice.

"My experience of it has extended over more than six years. In many important operations, especially those for THORACOPLASTY, we entirely gave up the use of the Carrell-Dakin Solution in favour of T.C.P.

"In my practice it has been found that the use of T.C.P. Liquid in treatment of chronic sinus cases, following old fracture of bones, in war wounds, or in cases of TROPHIC ULCERATION and ABSCESSES, ... the effects have been surprising.

"The most spectacular use of this preparation has only been known to me during the last 12 months, when it has been used internally, in combination with Colloidal Silicate of Aluminium, as an intestinal and gastric antiseptic; the curative effect of this combination in cases of HYPERCHLORHYDRIA, ... has been amazingly satisfactory.

"... A vast number of people of middle age suff digestive disturbances; have poor appetites; hav and intestinal spasms; and SLEEP VERY BA

"... If the medical profession generally co to try the effects of T.C.P. they would b success of this preparation, which is intestinal antiseptic.

"A suitable mixture is prepa loids Limited known as 'T EMULSION,' which is a co antiseptic Trichlorophenylme contai oidal a suitable adjuvant. or thrice daily emulsion in brea ext

BRITISH ALKALOIDS LIMITED 104, WINCHESTER BROAD STREET, LON

An Open INVITATION to the MEDICAL PROFESSION

IT is our sincere belief that in presenting Humanised Trufood to the medical profession and to the public we are offering the closest approximation to breast milk available.

This statement is made with due sense of responsibility, and it is our earnest desire that the medical profession take their own steps to corroborate its truth. Every facility will be given to the profession to visit our Creameries, examine our processes, and submit the product to any test known to science.

Clinical observation on infants fed upon Humanised Trufood confirms our belief that Humanised Trufood is the logical alternative to breast milk. Samples and literature will be gladly sent on request.

—the Prime Minister in a recent broadcast speech.

THERE is one cure: one protection against infection and disease that every mother and child should have. That is the protection of Marshall's Lysol—the antiseptic that is safe and sure for every case.

Marshall's Lysol is the only Lysol made from the original formula. A doctor who recommends Marshall's Lysol KNOWS that his patients will obtain a Lysol of unvarying strength and quality. That this is vitally important we need not stress. Every doctor and nurse knows that in midwifery, surgery, or cases of infectious disease, the highest grade antiseptic is absolutely essential.

MARSHALL'S *Lysol*

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Solving a Food Problem

HOVIS

Most nourishing Bread

After all the discussions as to the relative values of white, wholemeal, and various brown breads, it is satisfactory to have conclusive evidence at last.

Following many experiments by various research workers it is shown that no bread contains so large a percentage of Vitamin B as HOVIS, or is such an active agent for healthy growth when forming the basis of the diet.

As is now well known, even a partial deficiency in Vitamin B in the diet, if lasting for any length of time, impairs health, and, with children, prevents perfect development.

HOVIS, even in small quantities, provides sufficient vitamin in a digestive form as no other bread does, and it is liked by all.

Richest in Vitamin B

HOVIS Bread consists of White Flour with the wheat germ incorporated. It is this which gives it its special value, since the germ is the part richest in the Vitamin.

The "brownness" of bread is not a measure of its vitamin content. HOVIS does not contain bran, and is easily digestible.

Note the following figures showing the Vitamin B content of milling products and yeast in 100 g. dried bread:

White Bread	200
Wholemeal Bread	1,450
HOVIS Bread	2,600

The evidence is conclusive. For providing the maximum of nourishment economically no bread equals HOVIS.

ONE OF THE NEW GENATOSAN DENTAL PRODUCTS

GENOZO

BRAND

ANTI - PYORRHŒTIC TOOTHPASTE

The immunizing results obtained by Besredka and others by applying locally to the skin and mucous membrane wet compresses of dead bacteria have been confirmed by many competent bacteriologists. It is obvious therefore that a constant application of a vaccine containing the dead germs of pyorrhœa will produce a powerful local resistance in the gum tissues against pyorrhœtic and other purulent infections.

Based on these undisputed discoveries Genozo has been compounded by a surgeon dentist (also an M.D.) in co-operation with a distinguished bacteriologist. This toothpaste contains a special detoxicated vaccine, which is harmless and absolutely sterile, for the purpose of developing a local resistance of the gums to pyorrhœa. The other ingredients of Genozo harmonize with the recent findings of the profession on the injurious effects of certain substances contained in many dentifrices.

Because of the solvent action of strong alkalies on the tissues, soap has been excluded from Genozo, and as acids inflame the gums and put the teeth on edge by partially dissolving their lime salts this new toothpaste is non-acid. Genozo contains a polishing substance of a very fine nature and is powerfully antiseptic but entirely non-irritant. The daily use of Genozo leaves a high polish on the teeth without injuring the enamel and soon renders the gums firm and healthy.

A full-size Professional Sample of Genozo brand Tooth paste and samples for distribution to patients will be forwarded to any dental practitioner on request. The first Genatosan Dental Bulletin has already been sent to all registered dentists, but those whose copies have miscarried can still obtain a copy by writing to the Dental Products Department of:—

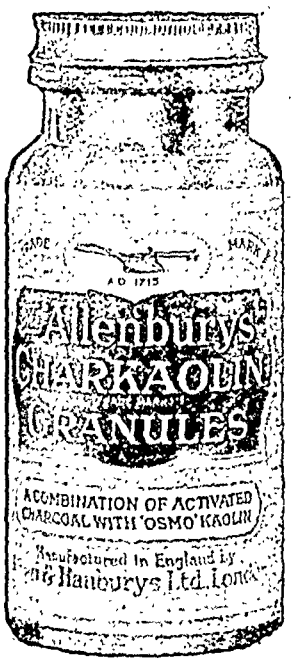
'CHARKAOLIN' GRANULES



A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

ALLEN & HANBURYS Ltd., Bethnal Green, E.2

Toast *and* Toast Racks superseded

The "RYVITA RACK" has displaced the old-time toast rack

Every day, more and more people are discovering how much more delicious, how much better than toast is "Ryvita Crispbread," the wonderful daily bread of Sweden.

"Ryvita" is made of rye—and nothing but rye—the only cereal from which this the true Crispbread can be made. The first people in this country to eat it were those most highly qualified to judge food values—doctors, dentists, and dietetic experts. "Ryvita" reached the multitude by way of the specialist, thus—despite envious imitators—establishing here "The Ryvita Crispbread Habit."

Eaten as your Daily Bread—"Ryvita," the Veritable Bread of Life, helps to make indigestion, constipation, malnutrition, and obesity unknown. Yet . . . so unique is this wonderful bread, that it is practically impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade. Notice how it sustains without cloying . . . how it gives you an exhilarating sensation of well-being and clear-headedness . . . how you work better, play better, and feel better on "Ryvita."

You will then understand why the old toast rack is now the "Ryvita" rack.

Send a postcard for generous FREE Sample to the Ryvita Company, 496, Ryvita House, 96, Southwark Street London, S.E.1. Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb carton; ½-lb., 10d.

Makes you fit—

RYVITA CRISPBREAD

keeps you slim

ACHLORHYDRIA IN INFANCY

Babies suffering from gastro-enteritis, measles, pneumonia, or any severe infection, cannot secrete a gastric juice of sufficient acidity to digest their food. The difficulty of "feeding up" during convalescence is due to this deficiency of acid. These infants have an intolerant digestive tract, but need a considerable amount of food in an easily assimilable form. By acidifying the milk with lactic acid, the buffer substances in the milk are neutralised, and the acid of the gastric juice liberated for peptic digestion.

The manufacturers of COW & GATE have surmounted the great difficulties of preparing lactic acid milk, and are offering to the medical profession two grades of dried milk, each containing one drachm of Lactic acid B.P. to one pint of milk.

ACIDAC

HALF CREAM LACIDAC

Contains 16% Fat.

SEPARATED LACIDAC

Contains 1% Fat.

Lactic acid milk has been employed both in infective disorders and in marasmus with great success. Using Lactic acid milk, one institution has reduced the mortality of marasmic infants from 78% to 26%.

The manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods.

PLURIGLANDULAR DISPENSING

The choice of pluriglandular formulæ for the various conditions in which organo-therapy is indicated is often difficult. There may be a considerable difference of opinion as to dosage, and physicians may from their practical experience decide something quite definite but which is probably not in accordance with the usual formulæ.

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland substances is always in stock and prescriptions can be promptly and accurately dispensed.

THYROSEX CO.

This is one of our recognised formulæ. It is put up in Tablets and in Elixir form, each dose representing Thyroid sicc gr. $\frac{1}{4}$, whole Ovary sicc gr. $\frac{1}{2}$, whole Pituitary sicc gr. $\frac{1}{10}$. It is designed for the treatment of the sexual disorders of puberty and for the neuroses and psychoses of menstruation. Full particulars of this and other formulæ will be found in our brochure "PLURIGLANDULAR FUNCTION," which may be had on application to

Evans' Biological Institute, Runcorn.

THE ECONOMICS of BARLEY WATER

¶ The virtues of Barley both in the feeding of infants and for medicinal purposes generally are widely recognised. That Robinson's "Patent" Barley is relatively cheaper than pearl barley is, however, unknown to many people.

	Wastage	*Cost of 1 pint of Barley Water*
Robinson's "Patent" Barley	*Nil*	0.19*d.*
Pearl Barley Loose	87.5%	0.25*d.*
Pearl Barley Packed	87.5%	0.40*d.*

The above figures are true in spite of the fact that Robinson's "Patent" Barley costs 1/3 per lb., whilst Pearl Barley costs 2½*d.* to 4*d.* per lb. The apparent anomaly is due to the fact that when Pearl Barley is used to prepare Barley Water at least seven-eighths of the quantity taken is wasted, whereas, in the case of "Patent" Barley, practically the whole of the Barley Flour is incorporated as Barley Water.

✡ ✡ ✡

¶ Apart from the question of cheapness there are two other reasons why Robinson's "Patent" Barley is preferable in use to Pearl Barley:—

1. The conditions under which Robinson's "Patent" Barley is cleaned and ground are such that the final product satisfies the most exacting tests of purity.

This cannot be said in all cases of Pearl Barley, which is sold to a large extent in the loose form.

2. The process of preparation of Barley Water from Robinson's "Patent" Barley takes 5-10 minutes at the most, whereas, in the preparation of Barley Water of a satisfactory strength from Pearl Barley the time taken is anything from 1½ to 3 hours. This difference in case of preparation is due to the finely ground condition of Robinson's "Patent" Barley.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

Messrs. KAYLENE, LTD.

April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

BI-LINGUAL COIN INSCRIBED IN THE TWO MOST ANCIENT SCRIPTS OF INDIA.—The bilingual coin here reproduced has the legend on the obverse in Brahmi, while the same legend is written on the reverse in Kharoshthi. Such coins bear valuable testimony to the pioneering spirit in ancient India during the time of social progress. The Western world knew nothing of the classical literatures of India before the last quarter of the eighteenth century, when the study of the Sanskrit documents began. The clue to their decipherment was provided by the ancient inscriptions and coin legends in Brahmi and Kharoshthi, the translation of which was made possible by the existence of coins of the Greek, Scythian and Parthian invaders bearing an inscription in Greek on the obverse and in Indian characters on the reverse.

VITAMINS A, B & D

HAVE ALWAYS BEEN IN

CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession — a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

A Lecture
ON
THREE CASES OF SPONTANEOUS SUBARACHNOID HAEMORRHAGE:
WITH ESPECIAL REFERENCE TO THE OCCURRENCE OF MASSIVE ALBUMINURIA AND KORSAKOW'S SYNDROME.*

BY
ARTHUR J. HALL, M.A., M.D., D.Sc., F.R.C.P.,
PROFESSOR OF MEDICINE, UNIVERSITY OF SHEFFIELD.

(*With Special Plate.*)

DURING recent years the subject of spontaneous subarachnoid haemorrhage has received increasing attention. Lumbar puncture has shown that this may occur without being necessarily fatal, and that its occurrence is indicated by a symptom-complex which in itself may be diagnostic. With this knowledge fresh cases are being more frequently recorded.

In each of the three following cases the diagnosis was made, not only by the characteristic mode of onset, but also by finding blood diffused through the cerebro-spinal fluid. Two were fatal. In one of these the diagnosis was confirmed at post-mortem examination, in the other a necropsy could not be obtained.

CASE I.

On the evening of November 10th, 1926, a young man, aged 26, was admitted to the Montagu Hospital, Mexborough, under the care of Dr. J. A. R. Lee, with the following history. He was returning home from his work as a bank clerk, and whilst walking along the street is said to have stepped off the footpath to allow someone to pass. In so doing he slipped and fell. It is also said that he had his hands in his pockets at the time and that he fell heavily head forwards. He did not attempt to get up. He was found to be unconscious, and was at once removed to hospital.

On admission he was completely unconscious; the limbs were in a condition of extreme rigidity. The arms were flexed across the chest so tightly that his clothes had to be cut off—the right arm being more rigid than the left. The legs were extended. The pupils were contracted. There was thought to be a slight facial paralysis, but this was uncertain. He remained in the same condition during the night.

The next morning his temperature was slightly raised (above 100° F.). There was some vomiting, and occasional twitching of the face. At 9 a.m. he was more conscious, looked about, but did not respond to questions. He is said to have spoken once. A sample of urine drawn off was found to contain a good deal of albumin.

When I saw him in consultation, about 10 p.m. of November 11th, the condition was as follows. He lay quietly on his back. The eyes were open and he looked about with a vacant confused expression. He did not show any response to questions or orders. The pupils were equal, of medium size, and reacted to light. There was occasional fibrillary contraction in the muscles of the left side of the face. The arms were flexed across the front of the chest, and any attempt at extension was strongly resisted. This was more marked on the right than on the left. No reflexes could be obtained in the arms. The abdominal reflexes were absent. The legs were rigidly extended—the right more than the left. The knee-jerks were brisk, also the ankle-jerks.

The plantar reflexes were markedly and briskly flexor on stimulation of the inner sole, and as markedly and briskly extensor when the outer margin was stimulated. In the right foot this persisted on repeated trials; in the left foot toe extension disappeared after a few repetitions. On simultaneous stimulation of the inner and outer parts of the sole the big toe remained motionless; the remaining toes were flexed.

The systolic blood pressure was 120, pulse 104. There was incontinence of urine. A catheter specimen showed a very heavy cloud of albumin. Except for a slight abrasion on the forehead, there was no evidence of any injury to the head. Lumbar puncture showed greatly increased pressure. The fluid was deeply blood-stained throughout. Unfortunately the specimen of cerebro-spinal fluid came to grief in transit to the laboratory, and therefore we have no detailed report on it.

On November 13th the temperature rose to 101° F. and remained there. The rigidity persisted. On November 15th the report was: "He answers 'Yes' and 'No' sometimes when questioned, but I think he does not understand the questions. He is taking a fair amount of milk and water. The urine yesterday contained less albumin and to-day only a faint trace."

He remained in much the same condition until death on November 18th, just a week after the attack.

A necropsy was made on November 19th by Drs. J. A. R. and R. T. Lee, who report as follows:

"We examined the skull very carefully and could not find any fracture. The whole surface of the brain was congested evenly, not in patches. There was some dark blood at the base of the skull in the region of the pons. It was clotted, and seemed recent. Nothing was found abnormal in any other organ."

A careful examination of the brain by Professor Douglas failed to show any aneurysm. His report is as follows:

"Generalized congestion of the pia mater, chiefly on the vertex. On the whole, the congestion is more marked over the surface of the left hemisphere than the right. It is more intense in the region of the left *motor area, comparatively slight* over the right. On the mesial surfaces the vessels are engorged rather more on the right side than on the left. The appearance is suggestive of acute changes in the meninges over the left frontal lobe. Similar changes are seen in the [illegible] and on the anterior part of the pons. [illegible] at the basal surface of the frontal lobe [illegible] marked on the right, where there is definite haemorrhage under the surface of the pia mater. No recent bleeding was seen in any of these parts. On cutting through the cerebellum a recent clot of blood about the size of a pea, and sharply defined, was found in the region of the inferior vermis, apparently just above the fourth ventricle in the middle line. It was semiliquid, and did not appear to be intimately mixed with tissue substance."

Portions of the brain from various parts were examined microscopically by Miss E. C. Eaves, M.D., who reports as follows:

Pathological Changes.

The vessels in the meninges were congested, and haemorrhages had occurred in different regions, most marked in the frontal lobe. In some areas the clot had become partly organized, but elsewhere the haemorrhage was apparently very recent, and extended a little way into the substance of the brain. Multiple small haemorrhages were present in the brain substance or around small or medium-sized vessels. The possibility has to be considered that the blood had tracked down the adventitial sheath of the vessel from the meninges. There were, however, situations in which a leakage of blood from the vessel could be observed. Haemorrhages were present in the corpus striatum and optic thalamus, as well as in the frontal lobe.

The changes in the tissue may be described as: (*a*) secondary to the haemorrhage; (*b*) primary changes.

(*a*) *Secondary.*—Some parts of the cortex appeared softer than normal. Microscopically there were numerous cells of the mesoglia type, and in some places there were groups of Körnchenzellen. The function of the latter is probably to aid in the removal of the debris of the softened nervous system. Friedmann,[1] in his experimental studies on the nervous system, has shown that these cells may appear in two or three days. The nerve cells exhibited a considerable degree of chromatolysis.

(*b*) *Primary Changes.*—The vessels of the meninges were thickened and stained in an abnormal manner with methylene blue (Fig. 3), as did some of the vessels in the nervous system. It was considered worth while to make an analysis of the cerebral cortex to ascertain if an unusual amount of calcification had occurred. The calcium amounted to 19.8 mg. per 100 grams of cerebral cortex, an amount about five times in excess of that found normally at the age of this patient,[2] and four times that found in old age accompanied by arterio-sclerosis. In some parts of the frontal cortex the vessels, and particularly the capillaries, seemed unusually numerous, even allowing for the fact that the congested and dilated condition would make them appear so. (Fig. 1.) This increased number of vessels was, however, limited to certain areas, and here the vessel walls were markedly different from the normal. There was proliferation both of the tunica intima and adventitia, and plasma cells were present. (Fig. 2.) There were many cells of mesoglia type in apposition to or near the vessel wall. Some of the blood vessels, and especially the very dilated ones, exhibited a thinning of the wall at intervals, although the vessel wall was elsewhere thickened. There was a slight increase of neuroglial cells.

The pathological findings are similar to those of a syphilitic arteritis. In this disease intracranial aneurysms may occur even in a young adult, and cause death from haemorrhage (Aldren Turner[3]). The limited area of the increased number of vessels is, however, difficult to explain. Nissl[4] has shown also that plasma cells are not pathognomonic of general paralysis, nor of syphilitic disease of the brain, but that they may be produced by any slight irritation, and are present in many diseases of the brain.

It is necessary to refer also to the experimental work of Friedmann.[1] He found that a destruction of [illegible] tissue may act as an irritant to the mesodermal tissues. In as little time as five to ten days the vessels of the irritated area [illegible] in number, and are thickened by proliferation of the [illegible] wall. The softening of the nervous tissue brought about by the haemorrhage could therefore act as an irritant and bring about a new formation of vessels in a limited area.

The possibility of an angiomatous condition may be considered. Calcification may occur to an unusual degree in this condition, as in two cases described.[2] However, haemorrhage was not a feature in these cases, although the patients, being epileptics, had numerous falls.

* Delivered before the Chesterfield Division of the British Medical Association.

The histological report shows that, although this man was thought to be in sound health prior to his fall, his intracranial arteries were definitely and considerably abnormal. The changes found in them are, in Miss Eaves's opinion, not inconsistent with a syphilitic origin. Unfortunately, owing to the loss of the specimen of cerebro-spinal fluid in transit to the laboratory, the means of confirming this or otherwise is wanting. At any rate, whether syphilitic or not, no aneurysm was found after a careful search of the hardened specimen, and the distribution of the blood did not point to one single focal origin. The presence of so large an amount of calcium in the brain points to changes of rather wide extent and long development.

Relation of Trauma to Haemorrhage.

This raises a point of much practical importance. Had this fall occurred whilst the man was at his work the question of compensation would almost certainly have arisen.

The history is that "he was walking along the road and, the footpath being narrow, he stepped off it to allow a lady to pass; that in so doing he slipped, and fell forward. As he had his hands in his pockets he could not save himself, and fell on to his forehead." There was only a slight abrasion on the forehead, and a careful examination of the skull showed that there had been no fracture or obvious injury to the skull. It is obvious that immediately before he stepped aside there had been no intracranial haemorrhage, for this does not begin without symptoms. On the other hand, immediately after he had fallen he was found to be unconscious and made no attempt to pick himself up, so that within that short time the haemorrhage must have been considerable.

Probably the immediate cause of the haemorrhage was the sudden muscular effort in trying to save himself when he slipped. This would be quite in keeping with the history often recorded in cases of spontaneous subarachnoid haemorrhage, in which the seizure occurs with surprising suddenness whilst lifting something comparatively slight, such as a coal-pan, or, as in a case under my care some years ago, hitting a four at cricket. If that is so, the actual fall would be not merely due to the slip but to the onset of haemorrhage, and with this rapidly extending he quickly became unconscious and rigid.

The second point of interest is that within a few hours of the attack this patient showed transient massive albuminuria. This sign was first recorded by Widal in 1903,[5] and since then has been observed from time to time. It is by no means always present. Symonds[6] points out that, although there is good physiological evidence that this may be due to disturbance of nervous centres concerned with renal secretion, hitherto in such cases the absence of renal disease has never been clearly established on clinical or post-mortem evidence. In this case the clinical evidence is that the albumin practically disappeared in a few days, and at necropsy the kidneys were found to be healthy.

In the second and third cases the point to which I would call attention was the presence of typical Korsakow's syndrome.

CASE II.—*Spontaneous Subarachnoid Haemorrhage in a Healthy Man of 36: Prolonged Pyrexia: Korsakow's Syndrome: Recovery.*

A married man, aged 36, always very strong and active, on January 6th, 1928, in the evening, whilst visiting at a house, felt a sudden intense pain in the back of the neck, much more severe than anything he had ever felt before. With great difficulty he managed to walk home. He vomited several times, but the pain persisted. Next day there was a temperature of 100°, headache, pain in the eyeballs, and stiffness of the neck.

With rest in bed he improved during the next day or two. On January 9th he came downstairs, but still felt pain and stiffness in the neck. The next day he stayed in bed and took a purgative as he had been somewhat constipated. After the bowels had acted he fell asleep and was sleeping quietly at 11.30. About 2 p.m., when food was taken to him, it was found that he could not be roused, and, in fact, was comatose.

I saw him about 3.30 p.m. He was deeply comatose, the respirations were noisy and irregular, of Cheyne-Stokes type. He was pale, slightly cyanosed, the eyes half closed, pupils small, divergent squint. The pulse was soft, small, and showed increased frequency. The legs were flaccid; no knee-jerks could be obtained, and no Kernig's sign. There was slight toe extension on the right foot, no response on the left.

The diagnosis of subarachnoid haemorrhage, due to a leaking aneurysm, was made. Lumbar puncture showed a free flow at rather increased pressure, deeply blood-stained throughout. The Wassermann reaction was negative.

On January 11th he was rather better; he had had a restful night, sleeping most of the time; he would wake up and respond vaguely when spoken to, but was very dull and heavy. The pupils were normal in size, equal, and reacted normally; there was no cranial palsy, and no head retraction. He passed urine voluntarily. Knee-jerks were still absent. Toe flexion on both right and left. The next day his condition was much the same—he was rather more restless. There was slight toe extension on both sides. Lumbar puncture again gave blood-stained fluid at slightly increased pressure.

During the next ten days his condition did not change very much; there was pyrexia every day, with a pulse always about 130. At one period catheterization was necessary, and this was followed by some cystitis, which soon passed off. During all this time the knee-jerks were constantly absent, whilst the plantar response varied. He was chiefly in a lethargic stuporose state, but could be roused, and he recognized those around him in a confused way.

On January 20th there was some ptosis and nystagmus, also slight Kernig's sign. The temperature returned to normal on January 25th; pulse 84, still very lethargic but clearer in between. A faint knee-jerk was obtained in the right leg for the first time on this day.

At the beginning of February he was having restless nights and sleeping all day. When aroused he was in a state of complete euphoria. He would smile, and say he was quite well; he had no idea of time or place; would begin an answer sensibly and at once wander off into confused nonsense. No nystagmus was present, and the fundi were normal. Knee-jerks were present, though very feeble.

He improved gradually, and by February 23rd he was coming downstairs each day. Mentally he presented the features of Korsakow's syndrome. There was smiling euphoria, together with unblushing accounts of what he had done, which were quite imaginary. Thus, in the presence of his wife and doctor, when asked what he did yesterday, he said at once that he had been out walking in the garden, although he had not been out of the house for six weeks. When corrected by his wife, he said, "Oh, didn't I?" and did not seem at all bothered. This mental condition continued for several weeks.

On June 20th, 1928, he was going about as usual, and driving his motor car for long distances (100-mile runs). He was sleeping and eating well. Slight headache and vertigo were present at times. His speech was slow and deliberate, with definite hesitation for words at times. Memory for recent events was not very good. His expression was rather fixed; there was slight tremor of the lids, but no nystagmus; knee-jerks were still only obtained on reinforcement.

At the present time, more than a year after his attack, he has been able to resume his full work, which involves a good deal of public speaking. He finds that for this he is obliged to rely on notes such as he did not require previously.

As regards the possible cause which set the bleeding going in this case it is said that just before going to make the call where it happened the man had been playing very vigorously with his little child—throwing it up in the air and lifting it on to his shoulders, etc. The second haemorrhage was no doubt set going by the effort connected with the act of free purgation. It emphasizes the importance of complete and prolonged rest after even the slightest subarachnoid haemorrhage.

This case appears to have been one of leaking aneurysm in which there was a primary small leak and a secondary larger but not fatal one.

The last of the three cases I have to record proved to be primarily a case of chronic granular nephritis, of which the subarachnoid haemorrhage was only an item. The presence of Korsakow's syndrome showed itself in rather a striking way.

CASE III.

A woman, aged 44, was brought into my ward on a stretcher on August 7th whilst I was going round, and before leaving I looked at her and asked some questions. She was rather confused, but said she had suffered from fits for several years, and that she was quite accustomed to them. I assumed that one had occurred in the street, and that she had been brought in because she was in a state of post-epileptic confusion. The next day when I saw her my house-physician said that lumbar puncture

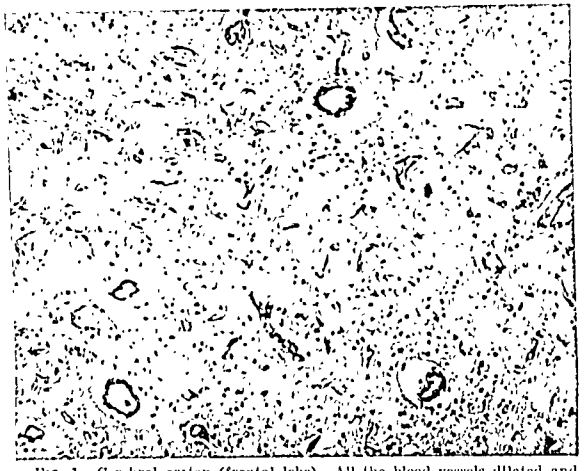

FIG. 1.—Cerebral cortex (frontal lobe). All the blood vessels dilated and more numerous apparently than normal. The spaces round the vessels may be due to faulty fixation. Magnification 60.

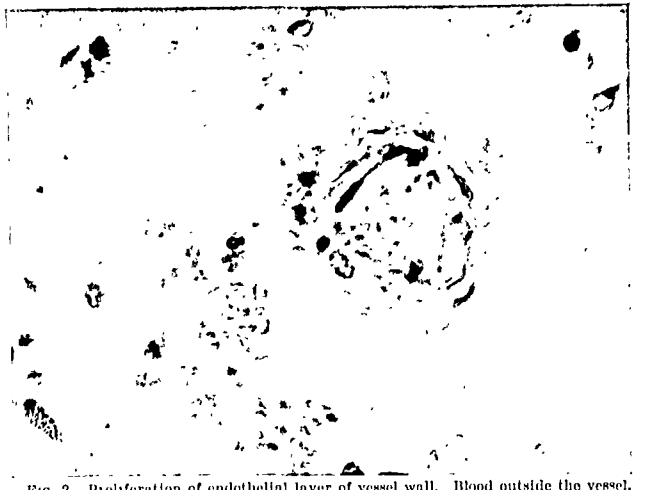

FIG. 2.—Proliferation of endothelial layer of vessel wall. Blood outside the vessel. There are two or three large microglia cells, only the nuclei of these being distinctly stained. Magnification 510.

FIG. 3.—Apparently calcified vessels, near corpus striatum; similar vessels in meninges. Magnification 60.

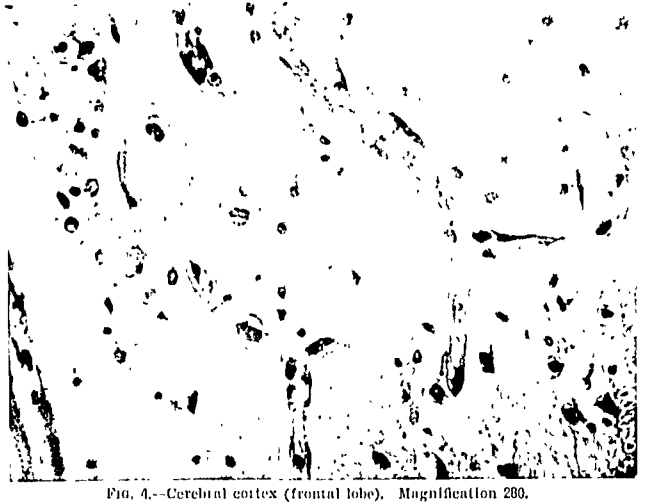

FIG. 4.—Cerebral cortex (frontal lobe). Magnification 280.

showed a blood-stained fluid at increased pressure, and that he had obtained the following history from her husband.

Three weeks previously she had sudden excruciating pains in the nape of the neck, with severe headache and vomiting for three days. After that she had pain behind the eyes, and headache. The evening before admission she had another sudden pain in the head, fell down unconscious, and remained so until shortly before coming in. She had never been subject to fits, and her statement to me the day before was entirely a confabulation.

During the next few days this condition of Korsakow's syndrome persisted; she would at any time, when asked what she had for dinner, give a detailed account of an ordinary plain dinner, with particulars elaborately filled in, although taking nothing but liquid food.

Further haemorrhages occurred, and she died on August 18th. She had albuminuria, retinal haemorrhages, and a blood pressure of 200/125. No necropsy was allowed.

The occurrence of Korsakow's syndrome in subarachnoid haemorrhage has been emphasized by more than one observer. Herman[7] of Warsaw, in a paper based on eighteen cases of subarachnoid haemorrhage seen in Flatau's Clinic, writes: "Chez ces malades apparait fréquemment le syndrome net de Korsakow." He states that it was first noted by Goldflam, and later by Mackiewicz.

Goldflam,[8] writing in 1923, says:

"In nearly all cases, at the height of the illness, certain psychic disturbances are observed, such as disorientation as regards time, places, and persons. These are generally neither severe nor constant. In some cases these disturbances come to the fore from the beginning, and consist of delirium, motor unrest, and confabulation, corresponding with Korsakow's syndrome; a good description is given by Flatau. This psychosis may outlast the fever and meningeal symptoms by weeks. Gradually the patient recovers from his delirium, corrects his confabulation himself, and the psychic symptoms disappear completely in, say, six weeks, as occurred in one case. In their place there remains for a time forgetfulness of actions just performed—for instance, the patients tell the same story many times over without realizing it. On the whole, it may be said that memory is well retained in such cases for events previous to the illness, but there is more or less complete amnesia, either for the whole duration of the illness, or for the first few days.

"It is known that Korsakow first described his syndrome in cases of polyneuritis, hence the name 'polyneuritic psychosis.' Since then the syndrome has been observed in a number of different conditions, from toxic and infectious diseases to cerebral contusion and incurable diseases, such as progressive paralysis and senile dementia. So far as I know, it has been described in subarachnoid haemorrhage only by Flatau, and yet it is present in all cases, more or less distinctly, not infrequently in a quite typical form. (It may be mentioned in passing that it is not found in cerebral apoplexy.) Whereas the prognosis in many of the conditions mentioned is absolutely bad, or grave, it is good in subarachnoid haemorrhage, for the psychic disturbances disappear completely. It may be assumed that the anatomical changes in these cases are of a temporary nature, and that the alterations in the cortex brought about by the extravasations of blood are capable of complete regression."

Mackiewicz's paper appeared in a Polish publication which I have not been able to obtain, nor has it been possible to trace the exact reference to Flatau's publication said to have been made in 1917.

The question of prognosis was of considerable importance in the second case. The somewhat prolonged persistence of mental symptoms caused considerable anxiety, as the patient held a highly responsible position involving much speaking in public, and his whole future depended on being able to continue this. In his case Flatau's views have been fully confirmed.

Symonds[6] has divided the cases into four clinical groups, on the following lines.

Group 1.—Sudden large haemorrhage leading to coma and death within a few hours.

Group 2.—Initial haemorrhage sudden and severe, but it is checked; initial coma gives way to mental confusion with severe headache; ends in recovery or further attack and death.

Group 3.—Initial haemorrhage small; headache and vomiting may lead to confusion, coma, and death; or the patient may recover.

Group 4.—Slow leaking; gradual headache and vomiting. [This group is somewhat hypothetical.]

Of the cases here recorded No. 1 would come under Group 2, whilst Nos. 2 and 3 would come under Group 3.

If there is extensive and advanced general arterial disease, syphilitic or other, there is no *a priori reason* why a vascular rupture should not occur in a meningeal vessel just as it does in one that is intracerebral. So also if the case is one of some general disease in which a tendency to haemorrhages is a recognized feature, such as purpura, haemophilia, scurvy, leukaemia, etc. Also in cases of embolic aneurysms due to septic infection the possibility of a meningeal bleeding must be always present. In all the above circumstances subarachnoid haemorrhage may occur, and the reason why it does so less commonly than intracerebrally is due to various factors which need not concern us here.

In some of the above groups of cases the immediate source of the bleeding has been a pre-existing aneurysm demonstrable at necropsy. In others, although no aneurysm is found, the site of bleeding is strongly indicated by the appearance of the meninges at and around some particular area, and even the ruptured vessel may be found—usually a very difficult matter. Apart from these groups, which together form the bulk of the cases of subarachnoid haemorrhage met with at necropsy, cases occur from time to time which cannot be included under any of these headings. Such cases have certain features in common. Thus they often occur in comparatively young people—early adult life; they usually come as bolts from the blue in persons thought to be in excellent health; they are accompanied by pyrexia for the first week or so; there may be subretinal haemorrhages. In a considerable number of the fatal cases of spontaneous subarachnoid haemorrhage of this class an aneurysm at the base of the brain has been found, and it has been suggested that such would be found more often were the examination made with sufficient care. These have been termed "congenital aneurysms," and it is assumed that they have arisen from some localized defect of development at this particular point, usually in the circle of Willis.

Parkes Weber[9] has pointed out that the term "congenital aneurysms" is inaccurate, and does not express what is meant, and that the assumption that there is an aneurysm in all these cases, whether it is found or not, overlooks the fact that a rupture may occur without necessarily being preceded by an aneurysmal dilatation, such as might occur in undue fragility of vessels or in a naevoid angiomatous condition, either of which might give rise to a spontaneous subarachnoid haemorrhage under some slight extra strain. Such alternatives seem to fit in rather better with some of those cases in which there are recurrent attacks of "leaking aneurysm" without a fatal result occurring. It is difficult to think that an actual aneurysm at the base of the brain which has once leaked can be in such a physical condition as to leak repeatedly at considerable intervals without a fatal bleeding ere long. On the other hand, it is quite conceivable that slight ruptures of vessels might arise in different parts of the meninges from fragile vessels or from a naevoid condition, and each in turn be sealed up and permanently closed.

The point at issue seems to be, are these cases of leaking "congenital" aneurysm occurring in younger persons merely a defect at one point of otherwise normal vessels, or are they a localized manifestation of a wider defect of intracranial vessels, possibly of developmental origin? If the latter, then whether the haemorrhage is preceded by an aneurysmal dilatation or not would appear to be a matter of more or less secondary importance, the primary cause being an abnormal state of the vascular development. So far as we have been able to review the literature of these cases we have found very few records as to the microscopical condition of the intracranial vessels other than some of the basal arteries. As a rule the pathological information available is limited to the naked-eye changes found at necropsy or the microscopic examination of the aneurysm itself. Case i, which clinically conformed in every point with the classical description of spontaneous subarachnoid haemorrhage, is therefore recorded because a detailed examination of the whole brain has been made and definite evidence of rather widespread vascular changes

has been found. It suggests that we are dealing with such a widespread abnormal vascularization of the intracranial area. My thanks are due to Professor Douglas and Miss Eaves for their valuable help in the pathological investigation of this case.

POST-ENCEPHALITIC DELINQUENCY.*

BY

RENÉ CRUCHET, M.D.,

PROFESSOR IN THE UNIVERSITY OF BORDEAUX.

IN a recent book[1] I recalled that during the war, from September, 1915, to February, 1916, first at Commercy and later at Verdun, as medical officer in charge of the neuro-psychiatrical services, I was struck by several cases of encephalomyelitis presenting peculiar mental symptoms. It was these mental forms of the disease that first put me on the road to discovering epidemic encephalitis, which, along with Moutier and Calmettes, I then called subacute encephalomyelitis. In a series of 208 patients studied at Commercy and Verdun, three had attracted my attention by their symptoms of fever, delirium, and mental confusion, which, without investigation, had been attributed to typhoid fever. One of these patients, suffering from amnesia, affective indifference, transient excitation, followed by asthenia and indolence, suggestibility, faulty judgement, stereotyped gestures, and negativism, resembled a case of dementia praecox. A fourth patient, a few weeks after influenza, had become almost demented and suffered from somnolence and intellectual collapse. A fifth had difficulty in speaking, an uncertain gait, headache, intention tremor, hemiparesis, and hemianaesthesia of the right side. A sixth, whose illness at the inception resembled, but was proved not to be, typhoid fever, suffered from diminished vision, clonic spasms of the eyes, unaccompanied by lesions of the fundus, and opisthotonos. Finally, a seventh had been seized with epileptic crises, with progressive mental deterioration, speech defects, and other symptoms too discordant to be attributed to cerebral tremor.

Eight further cases observed afterwards at Bar-le-Duc showed ill-defined mental symptoms—for example, impaired memory, intellectual deterioration, hebetude, and somnolence, but unassociated with modification of the cerebro-spinal fluid. In most of these cases an infectious state was noted, accompanied by febrile reaction, delirium, fatigue, inertia, and rigidity. Although the cause of the condition, in spite of researches then being carried out, was unknown, the patients improved under treatment, but several, after the acute phase had passed, had a fixed expression, slackening down of their actions and thought processes, and in some cases a tremor—symptoms which are singularly allied to those of what is now called epidemic encephalitis. As well as these purely mental forms I described convulsive choreic, meningitic, hemiplegic, ponto-cerebellar, ponto-medullary, acute ataxic, and anterior poliomyelitis forms. Of this polymorphism Professor Achard wrote:

"It might at first be believed, and was as a matter of fact believed for some years, that the disease described in France and in Austria in April and May, 1927, respectively, was not the same, so different were the two pictures drawn of it. Our fellow-countrymen had described a disease of very *diverse forms*; the Viennese author a disease very simple in its symptoms. . . . It was not until later that it was noticed that the disease could assume varied, changing, and unexpected aspects, and that this very diversity appeared to be one of its essential attributes. . . . Von Economo's description represents only one type of the disease. In strict justice it is the most exact description that has the greater merit, and it is Professor Cruchet's publication, which preceded von Economo's by a few days, that takes priority."

I cite these remarks less to return to the question of priority than to emphasize the importance of the polymorphism of encephalitis, a character which I considered essential from the beginning. This polymorphism, which is found in all the clinical forms of encephalitis, is an attribute of the mental forms with which I wish to deal more particularly.

The commonly described clinical syndromes of mental disorder can be recognized only with difficulty in epidemic encephalitis. The maniacal, melancholic, and chronic delirious syndromes are never clearly defined. I have known encephalitic patients with delusions of persecution, but modified, unobtrusive, and unaccompanied by auditory hallucinations. Much the same is true of the cases of megalomania, and of those patients whose psychoses assume the obsessive form. The most common type resembles dementia praecox, but even then with sufficiently marked differences.

I will cite a case representative of the conditions I have mentioned.

THE CASE OF ALIX.

This patient was aged 10 when, on February 10th, 1920, the first symptoms presented themselves; his teachers noticed that his eyelids drooped, and that he had a vacant expression. His vision was blurred and he had diarrhoea. On February 13th, at about 6 o'clock in the evening, he fell asleep during evening preparation. He had a raised temperature and was taken to the school *infirmary*, where, though he went on sleeping at night, it was observed that his body would every now and then move spasmodically. The next day he went to chapel, but fell asleep there. The fever, spasmodic movements, and blurred vision persisted, and that same evening he was taken to his home in a motor ambulance. On his arrival he was put to bed. He was febrile, delirious, restless, and the spasmodic movements continued. He had no sickness and the diarrhoea stopped.

On February 15th he was very tired and his tongue was parched; movement of the head was accompanied by pains at the back of the neck; his eyes were almost closed and staring upwards; he seemed blind, and could recognize neither the doctor nor his parents. His breath was very fetid, and he could only be roused from sleep with difficulty. Owing to pains in his neck and his loins he was unable to sit up in bed. Kernig's sign was slightly positive. An examination of his blood yielded no relative information. The next day his condition was worse; his teeth were clenched, and he had difficulty in swallowing. For a few moments during the morning vision returned, but he soon fell into a state of *torpor*.

On February 17th he was able to read a few lines from a newspaper, though it seemed to him to be printed in very small letters. His condition improved; the attacks of sleepiness were shorter, trismus was not so pronounced, his tongue less parched, and he was able to drink some milk without too much difficulty. He had, however, rather restless nights. On February 18th and 19th the fever increased, and restlessness once more became marked, but on the 20th improvement became evident and continued until the 22nd, when he was allowed up for a little while. Delirium was still present, but occurred for shorter periods and less frequently. During the following days he improved so rapidly that he was able to go out and ride a bicycle during the first week in March. He still had attacks of sleepiness, however.

Six Weeks Later.

When I examined him about six weeks later he seemed much better. He would get up about 6 or 7, ride his bicycle, and live a normal life till about 5 or 6 in the evening, when he would go to bed tired and fall asleep. At 7 he would be awakened for dinner, but sometimes he would be so overcome with sleepiness that he would keep mouthfuls of food in his mouth without swallowing them. Occasionally he would fall asleep after each mouthful. On certain days he had to be carried upstairs, undressed, and put to bed; his sleep was restless, and sometimes he was even seized with somnambulism.

The changes in his character were very remarkable; he had become irritable and insolent, and had violent outbursts of anger which were followed immediately by sleepiness. He would repeat the same thing over and over again, and would constantly put the same questions. When a story was read to him he would ask for the explanation of each word, even when he knew it quite well. He was unstable and changed his games frequently. Before his illness he was, if anything, mentally advanced for his age; now he was rather backward. His memory appeared to have deteriorated and his intelligence to have slackened. He complained of fatigue and headache at the slightest mental

* Abstract of a lecture delivered in English at the Universities of Glasgow and Edinburgh, on the invitation of Professor Currie and Professor Edwin Bramwell, April 22nd and 29th, 1929.

effort. His words were those of a child younger than himself; he spoke of going on a steamer or of becoming a naturalized American. He often had phobias. One day he thought that a heap of dust was a dead man and was afraid to approach it. If his sister's food fell on the ground he was worried that she might poison herself; if she had no hat, she was sure to get sunstroke, and so on.

On examination, his left eyelid was seen to be slightly drooping; the right eyelid was normal, but the droop in the left had noticeably increased since his recent illness. The left pupil was smaller than the right, which was slightly affected with mydriasis. Reaction to light was weak and vision blurred—in the right eye more than the left. There was no diplopia. Right eye vision was 10/10, left eye 3/10. His patellar reflexes were brisk.

It is needless to discuss the diagnosis. The case was one of encephalitis, of the lethargic type, such as was seen above all during the winter of 1919–20, the period of the first great French epidemic. The attacks of sleepiness, with their curious associated symptoms, were pathognomonic. It is worth considering the later stages of Alix's illness. As he grew he became more difficult and unmanageable; his physical development made rapid strides, but his mental state became increasingly unsatisfactory.

Three Years Later.

When I saw him in 1923 Alix was 13 years old, but so well developed physically that he looked 16. He was no longer affected with somnambulism, but his character had become progressively worse. He was irritable, insolent, quarrelsome, argumentative, boastful, would listen to no reproof, and insisted on having his own way in everything. In his narratives, shooting, fishing, rifle shots, and knife thrusts no longer had any terrors for him. He was, in fact, an excellent swimmer, and would plunge without hesitation into the Gironde, and, in spite of the strong current, remain in the water for hours on end, at the risk of drowning; or he would go out among the rocks, climbing the most impracticable places without realizing the danger.

This Hotspur had phobias in singular contrast to his intrepid nature. He was terribly afraid of microbes and had a mania for cleanliness; he was for ever washing his hands and scraping the soap he had used with a knife for fear that it had become contaminated. He changed towels immediately after using them, and if anyone else touched his towel he would throw it on the ground and immediately take another. He was afraid of spiders and saw them in his nightmares; he accused them of having urinated into his bed from the ceiling of his room. He had similar phobias for rats. He had become not only unpleasant in his behaviour—even spitting into the faces of people beside him—but often actually indecent.

A Year Later.

A year later, in 1924, a new factor appeared: he began to have spasmodic torticollis, which became progressively worse. At first there was no spasm when he was lying down, a little rigidity when he sat up, and twisting of the head and neck towards the right side only when he stood upright and began to walk. Any effort—for example, riding a bicycle—that brought into play the muscles in his arms and trunk exaggerated the condition. At this same period he experienced real difficulty in speaking, and was not always well understood. His instability, impulsiveness, and lack of will-power remained, and though for some time he was apprenticed to a locksmith, it was found impossible to teach him a trade. At the slightest reprimand from his mother he would become spiteful; sometimes he would strike her, being afterwards seized with remorse; or he would engage in a violent physical struggle with his father, become recklessly destructive, and shortly afterwards cry bitterly and make exaggerated manifestations of affection towards his parents. His petty indecencies were frequent, and he became gluttonous.

Present Condition.

We come now to March, 1929. Alix is 19 years old, tall, robust, full of physical energy, but his neuropsychic condition has scarcely altered. Neither the spasmodic torticollis nor the mental state has been modified by the numerous treatments followed for the past five years; these have included five pilgrimages to Lourdes, vibratory massages at the hands of various quacks, electrical, *x*-ray, and actinotherapeutic measures at a neurological centre, and the prescriptions of many doctors and specialists. Splints have not been successful as a remedy for the torticollis.

As soon as one meets Alix one is struck by this spasmodic torticollis. His head is turned to the right and droops in front, the chin resting on the collar-bone. The left sterno-mastoid muscle seems to be stretched, hard, and hypertrophied. With great effort he can lift his head and move it towards the left, but soon, by successive jerks, it turns again towards the right shoulder. To lessen the fatigue resulting from the constant effort to keep his head lifted, he presses on the right side of his forehead, or on the right superciliary ridge, but his hand gets tired in its turn, and he has to support it by leaning his elbow on some fixed point. This antagonistic gesture is well known to neurologists. The phenomenon is certainly of central origin, as I pointed out at the Annual Meeting of the British Medical Association in Edinburgh in July, 1927, when S. A. Kinnier Wilson read a paper to the Section of Neurology on tics and allied conditions. I stated that in 1907 I had already noticed the occurrence of Brissaud-Meige's "efficacious antagonistic gesture" in spasmodic states of non-mental origin, and that I had recently seen it in several cases of torticollis following epidemic encephalomyelitis.[2]

Alix's speech is muddled and explosive, and, especially at the end of the day, it is often difficult to understand him. He complains of getting tired fairly quickly; though he has retained his vigorous brute strength he has lost some of his agility and suppleness.

He eats at all times of the day, gluttonously, without control, and messily; at meal times he sits down to table, but every two minutes gets up, goes away, and returns, never satisfied. He is in constant conflict with his neighbours, before whom he behaves coarsely and without restraint. He likes to play the rich young man, changing his clothes and shoes as often as ten times a day. He loves the company of distinguished persons, to whom he writes ardent letters which he takes seriously. He spits wherever he happens to be, and has other objectionable personal habits. He is still quarrelsome, and if crossed will shriek aloud and roll on the ground, simulating a state of lethargy.

Discussion and Diagnosis.

All the post-encephalitic cases with psychic disorder, in children or adolescents, seem almost copied from each other. The true pervert, unlike the post-encephalitic pervert, displays an original evil impulse, which remains the same or becomes aggravated with age. He is persistent, incorrigible, cynical, and content to give himself up to his taste for morbid spitefulness. He delights in the refinement of suffering, remaining cold and insensitive to the moral pain he inflicts on those around him. He is often given to violence, thieving, lying, and pretence.

The post-encephalitic patient, on the other hand, becomes perverted only after his illness: his perversity is relative, as unstable as his character, irregular and fanciful. It is a question of playing pranks rather than of doing real evil. His cruelty is never coldly systematic, and it is unpremeditated. He is, moreover, affectionate, sensitive to reproof, and penitent. If he steals, lies, has violent fits of anger, or practises indecencies, it is more out of thoughtless imitation than of genuine vice. If he simulates, it is more like a capricious child acting without discrimination than knowingly to deceive those about him. His appearance, too, is very different. The look of the real pervert is hard, icy, deceitful; that of the post-encephalitic is gentle, sometimes shy or self-satisfied, smiling—the marks of a character which easily unburdens itself. Professors Euzière and Pagès[3] (Montpellier) have rightly insisted on the significance of this sensation of well-being, which, as they say, is so characteristic of Cruchet's disease.

The mental condition of the post-encephalitic delinquent strongly reminds one of dementia praecox: lazy, impulsive, incoherent, suggestible, and yet negativistic, given to affection, sudden escapades, offences against decency, and disconcerting failures of memory and judgement. His mental state at a given phase in his illness undergoes a sort of regression, but it is not a regression which goes on increasing until it ends in dementia; it stops at a period which varies according to the intensity of the encephalitis. Thus a child of 10 may regress to the mental age of 6 or 7, or even younger; a child of 15 or 16 may fall back to the intellectual level of 10 or 12. In certain cases, when the illness is over, the patient gradually recovers the abilities temporarily lost, and starts again on the upward grade towards the normal state. In other cases the psychic condition becomes fixed at the point of regression reached by the patient, or else it becomes stabilized at the age of the child at the time of its illness. Thus Alix's mother said, "In my opinion my son's brain has not progressed; it has remained as it was when he was 10, the age when he took encephalitis."

It must be added that the disease frequently implants in these children, even those stabilized at a given age, a form of morbid agitation and perversity, of which a weak

character is the essential sign. But if it be admitted that this perversity may remain markedly identical to that of the age of the beginning of the disease—for instance, as in the case of Alix—one can quite conceive its seeming considerably exaggerated when the patient has become an adolescent of 18, a young man of 25, and, with all the more reason, a man of mature age. One is thus tempted to see deep instinctive perversity where there exists only the puerile perversity of a weak-minded person. There lies the capital phenomenon, which it is easy to recognize as soon as attention has been drawn to it.

The perversity of the congenital pervert, in fact, increases with age; in the case of the post-encephalitic it may get better, or sometimes worse; most frequently it remains identical through the different periods of his life, but—and this is the essential point—with a mental debility which is henceforth constitutional. This state may improve in some cases, but frequently it changes for the worse or remains stationary; one is then obliged to put such patients in schools for nervous and abnormal children, like the one of which I am the head at Le Bouscat, near Bordeaux, or in reformatories when they are too difficult to look after and watch over. But in any case it is the state of mental debility which dominates the clinical picture.

Conclusions.

To sum up: what must be remembered is the variability of the post-encephalitic delinquent case, the fundamental basis of which is, above all, mental debility. One does not meet with distinct, unmistakable, categorical types of delinquents; they are irregular, undefined, and do not fit into any of the nosographic classifications which have been established up to the present. It would seem that the morbid histological diffusion of the encephalitic virus, which is so evident, involves a sort of regrouping of mental clinical states, which, for the moment, disorientate the mind and bring to it an impression of disorder.

And, finally, there can be recognized even in the enumeration of the descriptions of the mental clinical forms themselves, and of delinquency in particular, the polymorphism of encephalomyelitis, to which I drew attention in 1917, and which, after having been ill understood and rejected at that time, has to-day become a classic datum which is no longer even questioned.

THE PATHOLOGY AND TREATMENT OF CERVICAL GLANDS IN CHILDREN.

A REVIEW OF 330 CONSECUTIVE CASES.

BY

G. GORDON BRUCE, F.R.C.S.,

SURGEON, ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN; ASSISTANT SURGEON, ABERDEEN ROYAL INFIRMARY.

WHATEVER may have been the advance in social legislation in recent years, any surgeon connected with a children's hospital in Scotland must have been struck with the prevalence of cervical adenitis. It is proposed in this paper to consider the pathology and to give, if possible, the true indications for conservative and operative treatment. It is essential to picture the distribution of the cervical glands and to understand their structure. Figs. 1 and 2 may suffice.

Children up to 12 years of age are treated in the Royal Aberdeen Hospital for Sick Children; 330 cases of cervical adenitis were treated during the period reviewed—March, 1923, to March, 1927. Enlarged cervical glands were found to be more common in girls than in boys. The numbers were 183 and 147 respectively. The present series has been followed up for two to six years after leaving hospital. They may be divided into two main groups: (*a*) Acute and subacute non-tuberculous adenitis—74 cases (22.4 per cent.). (*b*) Chronic tuberculous adenitis—256 cases (77.6 per cent.).

Acute and Subacute Non-tuberculous Adenitis.

Although poor general health and defective hygienic surroundings are undoubtedly contributory factors, enlargement of glands is usually secondary to some local focus of inflammation. The primary causes were:

Infections of the nasopharynx, including the exanthemata	28
Infections of the scalp	24
Chronic otitis media	8
Dental caries	6
Septic abrasions of the face	6
Unknown	2
	74

Infections of the Nasopharynx.—The jugulo-digastric and neighbouring deep cervical glands are usually involved, the prevailing organism being the haemolytic streptococcus.

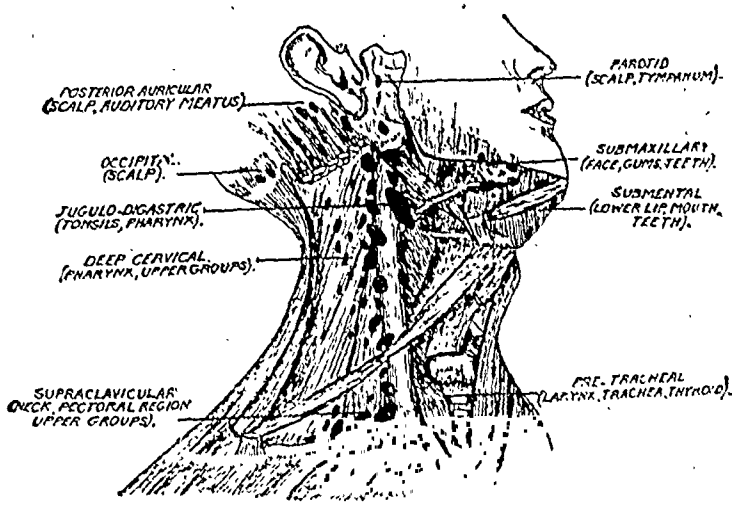

FIG. 1.—Distribution of the cervical glands.

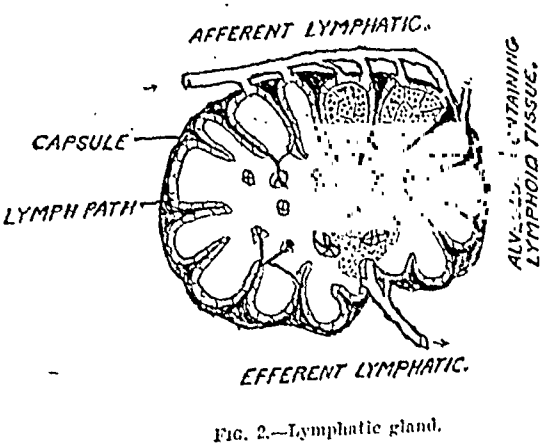

FIG. 2.—Lymphatic gland.

Infections of the Scalp.—Septic abrasions following trauma or chicken-pox and impetigo contagiosa commonly cause enlargement of the occipital and posterior auricular glands. They tend to suppurate rapidly. The infection is most frequently staphylococcal. In the poorer classes pediculi and "nits" account for many cases. It has been said that the swollen glands are secondary to abrasions caused by scratching, or to infection entering the skin by the biting of lice. Such views are open to doubt. The glands affected are usually the jugulo-digastric and upper deep cervical group. They are oedematous to the touch, and differ in type and distribution from glands secondary to suppuration in the scalp. Whether they are toxaemic in origin or not, it is exceptional to isolate organisms from the glands. "Nit-glands" readily subside on treat-

ment of the scalp with sassafras oil, but soon become necrotic if the scalp is left untreated.

Chronic Otitis Media.—Disease of the middle ear, unless tuberculous in origin, does not appear prone to cause enlargement of glands. Occasionally a chain of small glands is found along the posterior border of the sterno-mastoid muscle.

Dental Caries.—It is surprising how few cases of cervical adenitis can be traced to this cause. Glands are usually secondary to a suppurative periostitis. A single gland of the submaxillary or submental group is most commonly found.

Septic Abrasions of the Face.—Swelling of the submental and submaxillary glands is common in children under 3 years of age. Suppuration rapidly takes place, with a local cellulitis of the neck. Staphylococci from abrasions about the chin and lips account for most of the cases. The average duration of acutely inflamed glands when first seen was twelve days. They may be divided into two clinical groups.

Group A.—Glands which have appeared suddenly—a simple parenchymatous enlargement without any appreciable pathological change in response to a peripheral focus of infection. They feel soft, elastic, and are freely movable, in contradistinction to glands which are hard, solid, and adherent—the invariable signs of necrosis and commencing suppuration. There are no reliable means of judging the bacteriology of glands which recover with conservative treatment, although some idea may be formed from the type of primary focus present. Active treatment of any infected area is our mainstay. Local applications are of little value, and remind one of the days of charms and love potions. Operation can be deferred indefinitely, provided the glands show no progressive change, but they should steadily subside after a few weeks' treatment.

Group B.—Glands which have gone on to abscess within a few days of onset. They are common in very young children, and follow some febrile disturbance or untreated septic focus. The inflammatory process is usually limited to the anterior triangle of the neck. In the fulminating cases suppuration takes place in a few days, and the outline of the glands is soon marked by an astonishing degree of periglandular infiltration. The picture becomes that of a cellulitis of the neck.

The child's general condition and throat require careful attention: glycerin of borax is useful in babies, glycothymoline in older children. Iodine, ichthyol, mercurial ointments, etc., applied over acutely inflamed glands can be of no possible value, and frequently hasten destruction of the skin. Fomentations are most useful in acute cases. On any sign of fluctuation or impending respiratory distress the neck should be incised and free drainage established. Pathological tonsils should be removed later. The results of treatment of non-tuberculous glands are noted in Table I. The single fatal case ended with a streptococcal septicaemia.

TABLE I.—*Results, Non-tuberculous Glands (74 Cases).*

	Peripheral Focus only Treated.	Dissected	Incised.
Number of cases	32	5	37
Number traced	32	5	34
No glands remaining	24	3	27
Small glands, non-pathological	4	—	3
Recurrence of inflammation	4	2	3
Died	—	—	1

A child aged 2. Three days previously swollen glands were discovered in the right side of the neck. The mass rapidly increased in size, and symptoms of acute toxaemia with dyspnoea became evident. The neck appeared purplish-red, brawny, and indurated; this was particularly marked in the submaxillary region. On incising the neck no pus was found. The child died in forty-eight hours of an acute streptococcal septicaemia.

CHRONIC TUBERCULOUS GLANDS.

It is noteworthy that a family history of tuberculosis was only occasionally elicited. Many gave no history of antecedent disease. Infections of the fauces and nasopharynx, alone or in association with the exanthemata, preceded the occurrence of a very large number, scarlet fever, measles, or whooping-cough acting as predisposing causes to tubercle or lighting up quiescent tuberculous deposits. Haemolytic streptococci appear closely related to the activities of the tubercle bacillus. The following table gives the previous history in 256 cases.

No history of previous illness	99
Disease of the pharynx or nasopharynx	90
Dental caries	17
Measles	16
Scarlet fever	13
Whooping-cough	11
Chronic otitis media	5
Diphtheria	3
Retropharyngeal abscess	2

It is interesting to note that, with the exception of a few cases of tuberculous otitis media and mediastinal tuberculosis, no case gave a history or exhibited a sign of tuberculous disease elsewhere.

Tuberculous adenitis is frequently ushered in by acute symptoms during the course of some of the exanthemata when the outline of the glands is at first obscured by periglandular swelling. The latter gradually subsides, leaving typical discrete chronic glands. The slight improvement so frequently witnessed with conservative treatment at this stage does not herald a recovery in the gland tissues, but rather suggests that the infection has simply been localized within the capsule. When glands remain enlarged, necrosis has probably taken place in the alveoli during the original acute attack. It is common to find typical destructive tuberculous lesions after a history of three to four weeks. The more chronic type commences as small glands which gradually increase in size and number.

Bacteriology.

Mitchell[1] of Edinburgh, from his investigations into the prevalence of the bovine type of tubercle bacillus, found that cow's milk containing tubercle bacilli was clearly the cause of 90 per cent. of the cases of tuberculous glands in Edinburgh and district. He found the tonsils tuberculous in 35 per cent. The tonsils may be large, pale and obviously diseased, or small, embedded beyond the pillars of the fauces, and apparently normal. It has been proved that organisms may pass through the portals of the tonsils without the latter being diseased. Wood,[2] in an experimental study of the lymphatic drainage of the faucial tonsils, demonstrated, on injecting the tonsils by Gerota's method (Berlin blue and pure spirits of turpentine), that efferent lymphatic vessels from the tonsils passed directly to the jugulo-digastric and neighbouring deep cervical glands.

It is interesting to contrast the findings of Howarth and Gloyne[3] in the London area: they state that tuberculous changes in the tonsils were found in 5 per cent., and that tuberculosis of glands is a late infection and follows a previous invasion by the streptococcus. It appears probable that the prevalence of the bovine and human varieties of tubercle and the numbers of streptococcal cases

* Proved to be tuberculous on histological and bacteriological examination.

vary widely in different localities. This fact may well account for the extreme diversity of opinion regarding the treatment of cervical adenitis.

Tubercle bacilli reach the cervical glands along the course of the lymphatics from peripheral foci or find an entrance through the blood stream. (See Table II.)

Lymphatic Infections.—Of the 256 cases, 232 (90.6 per cent.) were considered lymphatic infections, as the distribution of the glands—jugulo-digastric group (78.1 per cent.), upper deep cervical (6.3 per cent.), submaxillary and submental (6.3 per cent.)—corresponded to drainage from local tuberculous lesions in tonsils, adenoids, and carious teeth. Further, it was found that no case belonging to this group showed signs of tubercle elsewhere either before or after operation.

Blood Infections.—The remaining 24 cases (9.4 per cent.) suggested blood infections from the glands involved—lower deep cervical (4.7 per cent.), pretracheal (1.6 per cent.), posterior auricular (1.9 per cent.), parotid (1.2 per cent.)—with associated tuberculous lesions in the mediastinal lymph nodes and the middle ear. Poirier and Cunéo[4] have pointed out that the supraclavicular glands receive no afferent vessels from the mediastinal glands. In tuberculous otitis media the parotid and upper deep cervical glands are usually enlarged. Swelling of the pre-auricular is more commonly found in tuberculous otitis media than in any other condition. Blood infections are more common in very young children under 3 years of age, and multiple tuberculous abscesses are of frequent occurrence. The prognosis is decidedly more unfavourable, particularly in glands secondary to otitis media, in infants. The only two deaths, occurring some time after operation, came under this group.

Pathological Changes in Tuberculous Glands.

In lymphatic infections the most marked pathological changes are found in the alveoli near the periphery; in blood infections the medulla is the first portion of the gland to suffer. In the early stages no change may be seen with the naked eye in a sectioned gland, but soon multiple greyish-white foci appear, caseation rapidly takes place, and each area becomes filled with semi-solid pultaceous debris or liquid pus. It is most important to bear in mind that a lymphatic gland is not a unilocular structure. During an attack of lymphadenitis the entire gland is swollen, but identical pathological changes do not take place in the whole gland nor in an equal degree in the different alveoli. Areas of caseation are multiple and so small that no sign of softening or fluctuation can be found. It is unusual for such areas to become completely confluent and for the gland to form a unilocular pus-sac exhibiting signs of fluctuation. More frequently only a few alveoli suppurate, while the intervening portions of the gland are replaced by a dense proliferation of endothelial and connective tissue cells. This accounts for the loss of elasticity and increased hardness of a pathological gland. It is surprising how universally clinicians fail to appreciate this danger signal.

Caseous material may lie quiescent within the capsule for several years before an extracapsular abscess forms; nevertheless it is well to remember that tubercle is not always chronic in its manifestations and that identical changes may occur in a few weeks' time. While the small septic foci steadily increase in size and threaten to involve the thickened capsule, successive attacks of periadenitis tend to bind the glands together and to form adhesions to the sterno-mastoid and digastric muscles, the deep veins, and the parotid and submaxillary salivary glands. Adhesions may be very dense where caseous material has locally eroded through the capsule. Ultimately the latter completely gives way, allowing the escape of pus and debris into the surrounding tissues and the formation of an extracapsular abscess. It is only after this catastrophe that "softening" can be appreciated. Signs of healing such as fibrosis and calcification, may be seen in an excised gland, but just as often areas of suppuration are found in other sectors of the gland. A natural recovery should never be assumed if the gland remains hard and palpable.

Clinical Types.

GROUP A. Simple enlargement ...	2 (0.8 per cent.)
GROUP B. Caseated glands ...	121 (47.3 per cent.)
GROUP C. Caseated glands with extracapsular abscess ...	111 (43.3 per cent.)
GROUP D. Caseated glands with sinus	22 (8.6 per cent.)
	256

An average of one year elapsed before a patient came for surgical treatment. Bilateral glands were present in 6.4 per cent. of cases. Gross destructive changes had taken place in 99.2 per cent.

GROUP A.—Tuberculous glands without alveolar caseation are rare. Only two cases were seen—large solid glands which persist in spite of treatment and which cannot be distinguished from caseated glands. On section they exhibit excessive endothelial proliferation. The numerous small glands found during the dissection of a large caseated gland may not show signs of caseation, yet the vast majority, when examined microscopically, show invasion by the tubercle bacillus.

GROUP B.—Caseated glands may be of any size from a pea to a hen's egg. They feel firm and solid, occasionally hard and knotty, certainly not elastic or soft. In them a definite and, I maintain, appreciable pathological change has taken place. The typical picture is an enlarged jugulo-digastric gland near the angle of the jaw with a few smaller glands along the posterior border of the sterno-mastoid muscle. The larger gland stands out prominently in the neck. The swelling waxes and wanes with the child's general condition, the state of the nasopharynx, and the changes in the glands themselves. Alternate attacks of swelling and periods of quiescence are almost diagnostic of intracapsular necrosis and caseation; the increase and decrease of the swelling corresponding to the onset and recovery of successive attacks of periadenitis.

I have never seen a gland, showing clinical signs of caseation, recover with any form of conservative treatment. Some time ago I referred a considerable number for heliotherapy, rather against my better judgement. The glands persisted or went on to abscess. Glands may appear to shrink to half their previous size with any form of treatment as the periadenitis subsides, but it is surprising how large a caseated mass may be delivered from the deep surface of the sterno-mastoid when only a suspicion of swelling is present.

Most of the tragedies of prolonged conservative treatment result from the failure to picture the pathology of such glands. How often has one heard it said that he or she thought it quite safe to leave glands because they were still hard and showed no sign of "softening"! Ninety-nine per cent. of all glands which have persisted for three months and have attained the size of a hazel nut show signs of caseation when removed by dissection. Solid glands frequently contain pus although they have lain quiescent for twelve months. The fact that they do not change is surely a plea for removal rather than for a further period of conservative treatment; moreover, favourable occasions for successful surgical measures do not remain so indefinitely. Unsightly incisions are too often the "late" cases. Here the patient or the medical attendant is at fault; the latter should set the time limit and be competent to say when the pathological changes preclude a natural cure—and he should be capable of doing so before gross abscess formation stares him in the face.

GROUP C.—"Nature is often hidden, sometimes overcome, seldom extinguished." Caseated tuberculous glands go on to abscess whether they be treated by the carbon arc lamp, tonsillectomy, or by local applications. The following clinical types are found. (*a*) A small slowly developing abscess beneath the platysma in relation to a chronic gland, a round swelling not adherent to the skin and standing out prominently in the neck. The mass may be freely movable, and is apt to be mistaken for an enlarged gland unless fluctuation be elicited. (*b*) A large group of glands with a small superficial abscess. (*c*) An infiltrated mass in which the outline of the glands is lost in the surrounding inflammatory reaction. The sterno-mastoid is usually,

densely involved, and fluctuating areas may be found in front of and behind the muscle. (*d*) A reddish-purple prominent swelling, the typical tuberculous abscess with the skin almost at bursting point.

Dissection is ideal, but often impracticable in the presence of gross suppuration. A surgeon has no qualms about embarking on a difficult dissection, and it is easy for him to be radical in his attack; but can he promise his patient the three essentials of success—no risk from haemorrhage, no injury to important nerves, no disfiguring scar? Provided the surrounding infiltration is not too great, the condition of the skin is the deciding factor. If he anticipates a soundly healed incision he should dissect. Scraping will cure many cases of abscess secondary to a single caseous gland. A large fluctuating mass should be thoroughly evacuated with a sharp spoon, and as much of the primary gland removed as possible. Residual masses may present a comparatively easy dissection at some later date. The removal of a few drops of liquid pus by aspiration is a method of treatment scarcely worthy of consideration. An infiltrated swelling, which precludes all question of radical treatment, may be benefited by heliotherapy.

GROUP D.—The clinical picture varies from a sinus leading down to a small indefinite mass of cicatricial tissue to one surrounded by an area of reddish-purple skin with large glands in the depths. "Sunlight" is worth a trial if no glands are palpable. Dissection is the proper procedure in most cases, as caseous glands await removal in the deeper planes of the neck. It may be difficult to secure a satisfactory scar if suppuration has undermined a large expanse of skin. Time may allow the skin to recover in a marvellous way, but mixed infections are common and skin recovers slowly.

Impressions on Conservative Treatment.

The armamentarium at a patient's disposal is truly amazing: a variety of paints and ointments, Bier's congestive treatment, Klapp's suction cups, cervical collars, tuberculin, tonsillectomy, *x* rays, radium, and heliotherapy. It is little wonder that many cases are far advanced and complicated by abscess when they have run the gamut of palliative measures and come at last for radical surgical treatment.

Surface Applications.—Nature is a powerful healer, and deserves most, if not all, the credit paid to iodine, ichthyol, mercurial ointments, etc. Counter-irritation is a myth. It is surprising that such applications are still in vogue. It was pointed out by Marnoch[5] twenty-three years ago that "when local applications reduced the size or caused the disappearance of swollen glands, it was very probable that one had to deal with glands which were not tuberculous at all, but which became inflamed from some irritation in the area drained by them, and that the decrease in size was due to the subsidence of the irritation and not to the applications."

Tonsillectomy.—We can take it for granted that the tubercle bacillus reaches the jugulo-digastric group via disease of the tonsils, and it is logical to attack the primary cause; pathological tonsils should be removed at the earliest possible moment. Nevertheless it is equally illogical to expect tonsillectomy to have any curative effect when advanced tuberculous changes have taken place in the glands. There are risks in dissecting with tonsils *in situ* if they are inflamed or harbour the all-too-prevalent haemolytic streptococcus.

Heliotherapy.—The brilliant results of Rollier in Switzerland have made many of us pause and wonder if surgical tuberculosis has not passed beyond our province. Treatment in the open air with exposure to the rays of the sun is always beneficial; unfortunately suitable periods are of brief duration. Artificial sunlight with the carbon arc or mercury vapour lamp improves a child's general condition, and small glands may disappear. Locally "sunlight" appears to hasten Nature's efforts at cure—that is, it accelerates the breaking down of caseous glands, abscess formation, and the discharge of pus. Taylor[6] quotes satisfactory figures in certain types, and comments on the more variable results in large solid glands. There is a risk of suppuration if caseated glands are irradiated, and one naturally hesitates to take that risk when a clean dissection is possible. I have removed glands after many months' irradiation and have found no change in typically caseated glands. This is not surprising, as the capsule is enormously thickened and there is no intimate vascular relation between a grossly pathological gland and the surrounding tissues. Heliotherapy is worth a trial in very early cases. Dr. Margaret Tod,[7] reviewing a series of cases treated in Edinburgh, states: "It will be noted that in no case has a cure been claimed, 'greatly improved' being the best result tabled."

Treatment Advocated.

The prophylactic and general treatment of tuberculosis lie beyond the scope of this paper. In deciding whether glands are tuberculous or not, one commences by excluding septic absorption from drainage areas corresponding to the glands involved—for example, treatment of the scalp in occipital and posterior auricular glands, tonsillectomy and amygdalectomy in the jugulo-digastric group, attention to the middle ear in the parotid group, removal of carious teeth, and attention to the hygiene of the mouth in submaxillary and submental glands. Palliative treatment, combined with every effort to improve a child's general condition, may be continued for two to three months if the glands steadily decrease in size. If they persist, it is highly probable that they are tuberculous. Mild cases may subside with prolonged rest in the country or after a course of heliotherapy. Whenever signs of caseation appear the glands should be removed during the earliest period of quiescence. One usually finds a single group, the jugulo-digastric series, and a complete absence of tuberculous disease elsewhere. Why risk the gradual involvement of other glands, an abscess which will endanger the symmetry of the neck, or a general dissemination of tubercle, when the single tuberculous lesion may be safely removed? Totally erroneous ideas have arisen from the comparison of tuberculous cervical adenitis, a local manifestation in 90 per cent. of cases, with tuberculous disease of bone, joints, and peritoneum—conditions which presuppose a general infection and which cannot be eradicated by operation. The universal improvement in a child's general health and freedom from tuberculous disease are good grounds for advocating radical treatment.

Surgical Treatment.

Tuberculous disease may transform the neck into a veritable maze of Daedalus. Dissections of cervical glands always require scrupulous care, are often difficult, and may be exquisitely dangerous in inexperienced hands. The operation can be safely performed at any age if the condition of the glands warrant their removal.

It is not sufficient to excise only the large masses, nor all palpable glands. Certain areas should be systematically explored: there are always glands behind the internal jugular vein and in the submaxillary region—they should be diligently sought for and removed. "Block excision" of large masses and chains of glands provides admirable museum specimens and may suggest the acme of surgical skill; unfortunately, such may be acquired at the expense of a segment of the spinal accessory nerve. It is often safer to split up large masses and to expose the nerve. The actual gland capsule should never be caught with forceps, as the larger glands contain pus and are easily ruptured. Tuberculous pus may be innocuous, but a streptococcal infection is occasionally superadded, and the less a surgeon smears his wounds with pus the better his results will be.

Dissections of glands complicated by abscess or sinuses may present formidable difficulties and may prove a very real test of skill and knowledge of pathological anatomy. Clear exposure and gentle handling will usually save the larger veins and spinal accessory nerve from injury.

Dissections in the Anterior Triangle.—The sterno-mastoid muscle stands out prominently in the neck. Between its anterior border and the line of the jaw lies an area in the shade crossed by two creases almost transverse in direction; here a scar may be almost invisible. The incision follows a skin crease and is made sufficiently long to ensure gentle handling and accurate dissection under full vision. The subcutaneous tissue and platysma are divided, leaving

a small portion of tissue over the convexity of the glands if there is any possibility of encountering pus. An elliptical incision surrounds a sinus or small superficial abscess. The external jugular vein is divided between ligatures. The sterno-mastoid muscle and surrounding structures are dissected away from the glands with a sharp scalpel. A small Mayo's scissors may be useful in exposing important nerves, but blunt and rough dissection with the finger or scissors in the depths is unsafe and liable to cause serious haemorrhage. The glands now lie in close relation to the digastric and stylo-hyoid muscles, the common facial and internal jugular veins, and the spinal accessory nerve. The internal jugular vein is exposed at a slightly lower level where the tissues are perfectly normal, the glands are elevated with forceps and are dissected off the veins, keeping the latter continually in view and catching small tributary branches before division. The wound is kept dry and free from staining. The spinal accessory nerve is found immediately beneath an enlarged jugulo-digastric gland. The deep glands along the outer border of the jugular vein remain to be tackled. A layer of fascia along the corresponding sector of the vein is divided in a parallel direction; two glands are usually found above the spinal accessory nerve and a long chain below. Although the wall of the vein may be in direct relation to the caseous interior of the gland, it is rarely necessary to remove a segment of the internal jugular vein. The submaxillary region is now explored. The salivary gland is frequently adherent to suppurating lymphatic glands, but is seldom grossly implicated. The whole gland or the most superficial portion may be excised. Care is taken of the mandibular branch of the facial nerve which passes along beneath the ramus of the mandible. Although Wood failed to trace an efferent lymphatic vessel from the tonsil to the posterior gland of the submaxillary group, I have frequently found this gland enlarged while dissecting the jugulo-digastric series. If the submaxillary glands are markedly involved, the submental region should also be cleared. All bleeding points are tied off with fine catgut and the wound is drained by a thin piece of corrugated rubber. Spaces in the neck cannot be obliterated by suture, and a collection of serum is fatal to a perfect surgical scar. The platysma is sutured with a continuous catgut stitch, which catches up a fraction of the subcutaneous tissue. The skin is closed with a subcuticular stitch of "gossamer" silkworm-gut. One or two interrupted sutures of the same material make the incision more secure. The drain is removed on the second day, and the skin stitches on the seventh day.

Dissections in the Posterior Triangle.—Care must be taken of the spinal accessory nerve, which crosses superficially from the posterior border of the sterno-mastoid to the trapezius. It is well to remember that the thoracic duct is liable to injury in a low dissection. Fortunately it is more often in the form of a delta than a single channel.

Scraping of Cervical Glands and Abscesses.—A small incision is made immediately beneath the abscess, not across the convexity of a red area of skin. The primary gland must be attacked in addition to the actual confines of the abscess cavity. The bad results so frequently quoted are not surprising, as such cases are often left to those of little or no experience. The cavity is packed with a narrow strip of gauze, which is removed on the second day. Pathological tonsils should invariably be removed. One expects to have to dissect later in cases of multiple glands, or where a large gland has broken down locally to some slight degree.

Immediate Operative Risks. (See Table III.)

Mortality.—The risk of a fatal issue following the dissection of neck glands appears negligible.

Haemorrhage.—Troublesome haemorrhage occurred on two occasions; in both the bleeding point was ultimately caught with forceps and ligatured. The usual causes of haemorrhage would appear to be inaccurate vision and rough handling.

Injury to the Thoracic Duct.—The duct or a tributary was injured in one case. The surrounding tissues were gently approximated by a purse-string suture, and no fistula resulted. Judd[8] reports 10 cases in a series of 668 dissections; all recovered, although one lost 60 lb. before the fistula closed. Edington[9] quotes one death and two recoveries. A further series of wounds of the thoracic duct have been reported by Cushing.[10]

TABLE III.—*Immediate Operative Risks.*

	Dissected.	Scraped.

Mortality	—	—
Haemorrhage	2	—
Injury to thoracic duct	1	—
Injury to nerves:		
Spinal accessory	—	—
Hypoglossal	—	—
Mandibular branch of facial	4	—
Wound suppuration	9	—

Injury to Important Nerves.—I have never been conscious of cutting the spinal accessory nerve, although I have often perilously nearly done so, nor have any of my cases to my knowledge suffered from paralysis of the sterno-mastoid or trapezius muscles. The removal of large masses of glands *en bloc* adds greatly to the risk. Clute[11] reports 12 cases of injury to the nerve in 140 dissections, and comments on the danger of "mass dissection." Judd[12] states: "We have injured and sutured the nerve on several occasions with no deformity resulting." In the present series the mandibular branch of the facial nerve was injured on four occasions. All recovered completely. Farr[13] states that the nerve can always be preserved by making a transverse incision three-quarters of an inch below the jaw and incising the deep fascia till the vessels and submaxillary gland are exposed. This is only true in cases where the glands are not adherent to the jaw or complicated by abscess.

Suppuration.—Nine cases developed an acute post-operative infection of the neck. Haemolytic streptococci were grown from the wound and tonsils in all cases; streptococci had also been isolated from a few of the glands. This distressing complication would appear to arise from operating on children while they harbour an active infection of the nasopharynx. One case had an acute streptococcal septicaemia which almost proved fatal.

This patient was a boy aged 9. Cervical glands had been present for six months, and they had rapidly increased in size. The neck showed an enlarged jugulo-digastric gland with two superficial abscesses. Pus was encountered during a difficult dissection, and the wound was drained. Signs of acute sepsis were manifest in a few days, and haemolytic streptococci were grown from the wound and tonsils. His condition steadily deteriorated, with daily rigors and the onset of a pleural effusion. Cultures from the blood stream and pleural cavity were positive. The wound was opened up and treated by the Carrel-Dakin method. Treatment in the open air, combined with massive doses of anti-streptococcal serum, ultimately defeated the infection. The pleural effusion yielded to aspiration.

End-Results following Dissection.

Number of cases	167
Number traced	183
Alive and well	183
Developed tuberculous disease elsewhere	0
Recurrence of cervical glands	6

The danger of generalized tuberculosis would appear immeasurably greater in allowing tuberculous deposits in the neck to run a natural course than by removing glands by dissection. Demmè,[14] reviewing twenty years' work in the Jenner Children's Hospital, Bern, treated 692 cases of cervical adenitis by constitutional measures, and found that 29.2 per cent. developed other forms of tuberculosis. All surgeons are agreed that the outlook is infinitely more favourable in children than in adults. Dowd[15] states that the incidence of pulmonary tuberculosis following dissection of neck glands in children is about 1 per cent., whereas Judd,[16] reviewing 600 dissections in adults, found that 5 per cent. developed tuberculosis of the lung.

Recurrence of Glands.—In the present series 6 cases showed post-operative glands; 3 of these required further

surgical treatment. Most of them were not true recurrences, but dated from the time of one's apprenticeship to surgery, when dissections were not so thoroughly performed. Excision of the gland-bearing fascia with a sharp scalpel is preferable to blunt dissection of individual glands with a Mayo's scissors. One case reported with several large glands in the anterior triangle after two previous dissections by a competent surgeon. On removing the glands for a third time a small abscess was found deep to the digastric muscle, and extending towards the pharyngeal wall. Any focus of infection may act as a stimulus to recurrence, and small particles of lymphoid material may grow and ultimately function as glands. It has also been said that lymphadenoid tissue, metamorphosed into fat, may resume its original lymphadenoid structure.

Condition of Scars following Dissection (see Table IV).—In 84 per cent. fine linear scars were present, with no suspicion of redness or surface prominence; of these, 40 to 50 per cent. were practically invisible unless the neck was closely inspected. A few broad scars are to be expected in cases reporting with abscesses or sinuses when the subcutaneous tissue had largely sloughed away. No case of keloid was seen. The pathology of this condition is still wrapped in mystery. The following are in my opinion contributory factors: an active untreated primary focus, a "bevelled" incision, inaccurate closure of the skin, the use of catgut skin sutures, and any swelling leading to stretching of the scar. The skin incision should be closed by a subcuticular stitch, which coapts the edges so accurately that they immediately adhere. No raw area should remain to ooze or heal by a process of superficial granulation.

TABLE IV.—*Condition of Scars following Dissection.*

	Cases.		Scars		
	Dissected.	Traced.	Fine linear.	Slightly prominent.	Broad or adherent.
Simple enlargement	2	1	1	—	—

Results of Curettage.

Of 111 tuberculous glands complicated by abscess, 32 were dissected,* the remainder were scraped, with the following results:

No glands remaining	38
Small glands, non-pathological	13
Required dissection later	14
Pathological glands still present	7
Untraced	5
Died later	2
	79

Two infants, suffering from tuberculous mastoiditis with secondary glands and abscesses, succumbed to tuberculous meningitis a few months after operation. The spread to the meninges would appear to have taken place directly from the petrous bone. In neither case was any radical operation performed on the ear or mastoid cells.

I find that 50 per cent. of tuberculous glands complicated by abscess ultimately require dissection, that 34 per cent. recover completely after curettage, and that the remainder have small palpable glands which do not appear pathological. Cases of chronic abscess arising from a single caseous gland have a reasonable prospect of cure, as the smaller associated glands subside if safeguarded from further bouts of infection by removal of tonsils, etc. One naturally wonders if a follow-up period of two to six years is not rather brief, but end-results in tuberculous adenitis are akin to malignant disease—there is no time limit to recurrence. It is by no means easy to be dogmatic about small glands remaining after curettage, as I find the jugulo-digastric glands palpable as small ovoid bodies about the size of a haricot bean in 85 per cent. of healthy children, and smaller glands along the posterior border of the sterno-mastoid are not uncommon. Dowd,[17] commenting on similar nodules, remarks: "I have watched nodes of this kind year after year, and have hardly ever seen them increase in size and have frequently seen them subside, a few have been removed and almost without exception have proved to be hyperplastic."

I maintain that minute glands which are perfectly soft and not larger than a bean can be safely left to Nature; other observers might deem them pathological—then they present the easiest of dissections if one is obsessed with the idea of removing the last shred of palpable lymphatic tissue from the neck.

CONCLUSIONS.

1. As seen in a surgical out-patient department 10 per cent. of glands are likely to recover with treatment of a peripheral focus of infection. Such glands are probably not tuberculous.

2. Necrosis and caseation take place rapidly in tuberculous glands.

3. The signs of caseation are increased hardness and loss of elasticity, not "softening" as is generally thought. Softening or fluctuation indicates an extracapsular abscess.

4. Palliative measures may allow the subsidence of periadenitis, but have no influence on the intracapsular substance of the gland.

5. The fact that 51.9 per cent. of tuberculous glands are complicated by an abscess or sinus suggests that conservative treatment is usually unduly prolonged.

6. Tuberculous glands should be removed by dissection whenever signs of caseation become manifest; the presence of an abscess is no contraindication.

7. Curettage gives satisfactory results in selected cases.

I have to acknowledge my indebtedness to Dr. E. A. Johnston and Dr. T. O. Morrison for their help in arranging the "follow-up" of patients, and to Miss Kathleen I. Stewart for her assiduous care and skill in the post-operative treatment of my cases.

SOME ASPECTS OF THE TREATMENT OF RHEUMATOID ARTHRITIS.

BY

A. H. DOUTHWAITE, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

In briefly outlining the most important forms of treatment of rheumatoid arthritis, I would draw attention particularly to the benefit ensuing from consideration of the mechanical aspects of the affliction. Drug and vaccine therapy are scarcely considered, for both are strongly represented in current literature, and neither has proved of much efficacy.

So long as it is held that the presence of focal sepsis is the chief or only etiological factor, so surely shall we make no progress in the treatment of the disease. Prior to the advent of the wave of enthusiasm for bacteriology, clinicians directed their attention to the constitutional abnormalities of the individual as a whole. Resulting therefrom came the masterly accounts of the disease, such as that of Kent Spender,[1] unsurpassed in accuracy of clinical observation by modern writings. When the medical mind focused on the dangers of dental and tonsillar sepsis, the concurrent

diathetic and acquired widespread deviations from the normal were overlooked. The result is that the outlook for the rheumatoid patient is little, if any, better to-day than it was fifty years ago. Too many of our patients have been rendered edentulous only to suffer the miseries of disturbed digestion and steadily stiffening joints. Such failures may be explained by postulating the presence of microbes in the interstices of the jaw, and operation advised to remove doubtfully infected bone. Pulmonary abscess is then a common sequel.

If, however, we pause to review the aggregation of cases loosely termed "chronic rheumatism," we find that as a rule they may be separated into three clinical types.

1. Rheumatoid or atrophic arthritis, a disease occurring largely in females of reproductive age and characterized by little or no pyrexia, low blood pressure, and unstable pulse rate,[2] scattered pigmentation of the skin,[1] on a basic waxy pallor, generalized wasting in addition to pronounced atrophy of the muscles about the affected joints, visceroptosis, hypochlorhydria, exaggerated tendon reflexes, and symmetrical swellings of smaller joints, particularly those of the fingers. The skin over the affected articulations is pale and atrophic, and local tenderness to pressure is never a striking feature. With the exception of increased translucency, bony change is absent for months or years.

2. Infective arthritis (excluding pneumococcic, gonococcic, etc.) occurs with equal [illegible] sex. It is usually associated with [illegible] sepsis in the mouth or maxillary antra. Pyrexia is the rule, and the affection is asymmetrical, involving larger joints—for example, wrist, ankle, and knee—than those attacked in the atrophic type. There is local redness and tenderness of considerable degree, but none of the general constitutional abnormalities noted in the first class. The condition clears up spontaneously, or is greatly ameliorated, on elimination of the infected foci.

3. Osteo-arthritis, or hypertrophic arthritis, occurs usually after the age of 40, and attacks otherwise robust and commonly obese individuals who exhibit good muscular and visceral tone. The acid content of the gastric juice is a high normal. The joints commonly affected are those of the knee, hip, and fingers, but there is early enlargement of the bones with osteophytic outgrowths, and obvious lipping of the articular margins is demonstrable by *x* rays. There is no constitutional disturbance, and the disease progresses slowly and often painlessly for many months.

Predisposing Factors.

Inquiry into the previous history of patients with rheumatoid arthritis reveals a series of deviations from the normal, such as is not found in the other types. Thus the subjects have always been of spare build, intellectually efficient, but lagging behind their fellows in physical prowess. They have suffered from the cold, and chilblains on blue, clammy extremities have recurred with monotonous regularity winter after winter. Llewellyn[3] has drawn attention to the frequency of mucous colitis, urticaria, blanching of the fingers, and erratic sweats which characterize childhood and adolescence. It is difficult to determine the point at which rheumatoid arthritis actually develops. Loss of weight and vigour often precede the onset of joint swellings by many months, and when articular involvement is finally apparent it is usually at first transient in nature, a feature of differentiation from the proved infective forms.

Metabolic Errors.

Metabolic changes have been demonstrated in rheumatoid arthritis. The chief of these is deficiency in the oxidative processes occasioned, it is believed, by the existence of large areas of vaso-constriction and capillary stasis. Resulting therefrom are decreased sugar tolerance and relative increase of neutral or imperfectly oxidized sulphur in the urine.[4] It is stated[5] that these abnormalities can be corrected by the use of vaso-dilators. If this be the case, it supports the theory that the fundamental disturbance of the disease is that of sympathetic instability. It has been postulated that the basis of the sympathetic instability lies in a disturbance of the endocrine system, particularly in the direction of hypothyroidism. The arguments are suggestive, but not yet convincing, for many of the symptoms of rheumatoid arthritis are rather those of hyperthyroidism, and I have rarely found a basal metabolic rate of abnormally low level.

Space does not permit of a full discussion of this interesting problem, but enough has been written to emphasize the fundamental truth that rheumatoid arthritis is a disease developing on a grossly abnormal soil, and that inattention to this fact must militate against the production of effective cure.

TREATMENT.

Diet.—In the acute stage a bulky diet poor in nutritive value should be prescribed. Such consists largely of fresh fruit and green vegetables. After two weeks, fish, chicken, and red meat may be added, but starchy and saccharine foods should form a small proportion of the total in view of the noted inability to deal adequately with glucose.

Drugs.—Medicinal treatment is of small value. Apart from symptomatic treatment for the relief of pain, preparations of iodine and thyroid gland are chiefly favoured. The effect of the latter in stimulating the sluggish metabolic processes explains any improvement which may follow its use.

Elimination of Sepsis.—The utmost caution should be exercised before advising the removal of teeth or tonsils suspected of infection. In a disease presenting abnormalities of skin, gastro-intestinal, muscular, and vascular systems, it is scarcely to be expected that healthy teeth would be found in an otherwise diseased individual. Recession of the gums, the formation of pockets, and *x*-ray appearances of early infection are the result, not the cause, of rheumatoid arthritis, and to advise wholesale extractions is as illogical as to counsel removal of the colon on account of sluggish peristalsis. Both conditions subside *pari passu* with recovery from the general disease. On the other hand, frank sepsis should be eliminated, for its presence will lower the bodily resistance, and the absorbed toxins may act indirectly, through damage of the endocrine system, in producing arthritis. It is of peculiar interest to note that Pemberton[5] found infected foci in 70 per cent. of his 1,100 cases of chronic arthritis, but the number of recoveries was three times as great in those in which sepsis was allowed to remain as in cases from which it was eliminated.

Application of Heat.—Probably the relief derived from thermal treatment by radiant heat baths, diathermy, dry air baths, and hot wax applications is largely referable to the improvement which they produce in the peripheral circulation. I have achieved the best results by the use of a cabinet heated by electric light bulbs and into which air, previously dried by passage through chemicals, and impregnated with a volatile rubefacient, is pumped. The patient is given one-tenth of a grain of pilocarpine hypodermically before entering the cabinet. Profuse sweating occurs, but, owing to the dryness of the air, the perspiration evaporates rapidly, and the patient emerges refreshed rather than in the state of sodden exhaustion produced by many other forms of heat. General massage is carried out immediately after each treatment. Within a few weeks there is a noticeable improvement in the condition of the skin and joints, and the patient is relieved from the wearying pains and insomnia which have caused so much distress in the past. The method of application of hot paraffin wax has gained prominence of recent years, and bids fair to supersede many of the older forms of thermal treatment. Owing to the non-conducting nature of this substance, it can be applied at temperatures of 120° to 170° F. to the entire body without producing a burn. Additional safety is ensured by the fact that a cushioning effect is produced by the inclusion of a thin layer of air between the wax and skin. Heat loss is very slow, thus a constant high temperature can be maintained for half an hour or more before the solidified casing is removed and the abundant sweat wiped off.

Use of Splints.—Mechanical appliances for the control of joint movements are required (*a*) in the acute stage of the disease in order to prevent contractures and to allay pain; (*b*) in the late stages when the patient suffers from the crippling effects of periarticular and intra-articular

adhesions. In the former case light splints should be applied to hold the shoulders abducted, elbows semiflexed, forearms incompletely supinated, wrists dorsiflexed, fingers extended with radial deviation, thumb slightly flexed and adducted. As regards the lower extremity, if the hip-joints are affected the patient should lie flat. Great care must be exercised to avoid hyperextension at the knee-joints; the foot should be held at right angles to the leg. Once the limbs are immobilized, muscular spasm subsides and relief from pain invariably follows. After a week it is usually advisable to remove the supports daily and to apply gentle massage and cautious passive movements in order to avoid stiffness. With this one must be content until the acute symptoms have subsided, when treatment by dry air baths, massage, and active movements may be instituted.

In the late stages of the disease little or no activity is present, and we are confronted with the mechanical disabilities resulting from the ravages of an affection now almost extinct. If the joints have been allowed to become fixed by fibrous tissue their mobility must be restored by graduated manipulation. In the case of the lower limbs, however, this process is useless unless the weight of the body be subsequently transmitted through callipers from pelvis to ground. Various appliances have been devised for this purpose, and may incorporate an adjustable extension for the knee-joint. By their use the patient is enabled to walk with little or no pain, and the previously atrophied muscles rapidly regain their lost bulk and tone.

Manipulation.—This is an essential adjunct to the mechanical treatment in all save the acute stage. It must be borne in mind that pain and swelling in a joint are not necessarily signs of active disease, but commonly result from the irritating action of adhesions. It is, in fact, remarkable how soon symptoms subside after the affected joints are moved with rupture of these bands. Patients apparently hopelessly bedridden are restored to relatively painless activity by a procedure which is still regarded by many as fraught with danger. Actually, instead of lighting up the disease by forced movements, the very reverse takes place, provided, of course, that the manipulation is carried out by those versed in its technique and aware of its dangers.

The ground gained by these procedures must not be lost *by inattention to the details of after-treatment.* It is essential that the increased range of movement be preserved, and this is best attained by encouraging active movements, which, in certain joints, may be aided by taking advantage of the inertia of a weight tied to the distal end of the limb. All these exercises must be watched and controlled by a masseuse, on whom the onus of producing a cure rests almost as heavily as on the physician.

RAPIDITY OF HEALING OF A GASTRIC ULCER.

BY

RALPH MORTON, M.B., F.R.C.S.ED.,

HONORARY SURGEON, LOUTH HOSPITAL, LINCS.

(*With Special Plate.*)

THE following case is worthy of publication in the light of the recent discussion with regard to the rapidity of healing of a gastric ulcer under intensive alkali treatment.

A shop assistant, aged 24, was admitted to Louth Hospital on November 23rd, 1928. His story was the typical one of pain after food, on and off, for over a year. He had recently become progressively worse, and at the time of admission stated that he had not been free from pain during the preceding ten days. He was emaciated, weighing only 7 st.—his usual weight being about 9½ st. He was tender on palpation in the epigastric region, and presented the general appearance of having suffered a good deal.

The radiograph taken the day after admission (Fig. 1) shows a large ulcer on the lesser curvature of the stomach. He was put on a rigorous diet (Sippy[1]), combined with intensive alkali treatment as described by Professor MacLean.[2] Under treatment he improved rapidly. In about three days he was free from pain, but tenderness persisted for about three weeks.

A second plate was taken a little over a month later, and this (Fig. 2) shows that the crater is rapidly filling up.

A third plate, taken one month later, shows that the lesser curvature of the stomach has almost regained its normal contour.

The patient now enjoys absolute freedom from pain, can take normal diet, and his weight has increased to 9 st. 7 lb.

Here we have a large ulcer which has rapidly been brought into a quiescent state; I shall not at such an early date say *healed. It illustrates the fact that* large ulcers can be rapidly brought into a healing condition under intensive alkali therapy; but in my opinion such ulcers are not of a deep or penetrating variety. I agree with Barclay[3] that it is impossible to tell from a radiograph whether an ulcer is of a penetrating variety or not; much of the appearance of penetration is due to heaping of the gastric mucosa combined with surrounding inflammatory exudate. The extent of the disease can only be judged in such cases by correlating the radiographic appearances with the actual clinical symptoms and signs.

I take it that the cases described by Professor MacLean which rapidly responded to intensive alkali treatment were of this nature. At the same time I agree with Lord Moynihan[4] that real penetrating ulcers would not thus rapidly disappear in a month or so.

Intensive alkali treatment combined with dieting and rest certainly does give relief in cases of early or shallow ulceration, but in the case of large penetrating ulcers surgical intervention is still the only hope of cure.

COEXISTENCE OF LYMPHADENOMA AND TUBERCULOSIS.

BY

T. KRISHNA MENON, M.B., C.M.,

HONORARY PHYSICIAN, GENERAL HOSPITAL, MADRAS;

AND

T. BHASKAR MENON, M.B., M.R.C.P.

(Department of Pathology, Medical College, Madras.)

(*With Special Plate.*)

THE possibility of lymphadenoma and tuberculosis coexisting is well recognized. Ewing has pointed out that tuberculosis follows in the wake of lymphadenoma, and Ziegler estimated that 20 per cent. of these patients died of miliary tuberculosis. It has, indeed, been held that the two diseases are identical. Sternberg first put forward the view that Hodgkin's disease was a form of tuberculosis, due, probably, to infection with an attenuated form of the tubercle bacillus. Clinically, cases occur in which the two diseases are almost indistinguishable. In the morbid histology of tuberculous adenitis a type is recognized without definite giant cell systems and in which endothelial hyperplasia is the characteristic feature. It is well known that an endothelial hyperplasia may be the sole feature of early lymphadenoma, a point which is emphasized by Christian and Warthin. Even Andrewes, though he denies the identity of the two diseases, considers it is difficult to *distinguish atypical lymphadenoma from a typical* tuberculosis.

We do not intend to lay any great stress on this view, but the occurrence of tuberculosis in cases of Hodgkin's disease is of great interest, since both may present lesions which are difficult to allocate. This is particularly so since there occur in lymphadenomatous glands in the late stages certain yellowish-white areas which are referred to by Ewing as "necrotic foci" and by Longcope as "areas of necrosis." The difficulty arises in distinguishing them from areas of caseation, and the question may be asked

whether these necrotic foci are really due to a mixed infection with the tubercle bacillus, or whether there is in lymphadenoma a type of "caseation" similar in certain aspects but differing in others. This latter view is of importance since, if this is so, the analogy with other infective granulomata like syphilis, tubercle, and actinomycosis becomes more striking, for in all these conditions we have alteration of the normal structures by endothelial and lymphoid tissue with the presence of giant cells, followed later on by "caseation" and by sclerosis.

The following case of coexistent Hodgkin's disease and tuberculosis is of interest since these necrotic foci were present in the glands.

A man, aged 30, was admitted under the care of one of us in the General Hospital, Madras, on August 28th, 1927, with a history of enlargement of the glands in the neck, pectoral region, and axilla of five months' duration. He was sent to the surgical ward for excision of a gland for pathological report. The report was "lymphadenoma," and the patient was subsequently readmitted to the medical wards on September 11th. He was then complaining of difficulty in swallowing, possibly from pressure of the glands in the neck. The glands in the parotid region were also enlarged. There was, however, no dyspnoea, loss of voice, or enlargement of the superficial veins, or any feature suggestive of a mediastinal growth. The chest was, however, asymmetrical and there was slight fullness in the second and third interspaces on the left side. From the first a dullness on percussion of both sides of the chest was noticed and on auscultation a few rales could be heard. The heart showed a slight softening of the first sound in the aortic and pulmonary areas. Throughout his stay in hospital there was a remittent pyrexia, with, however, no periods of apyrexia. Puncture fluid from one of the glands showed marked eosinophilia. The Wassermann reaction was negative.

The blood on admission showed 1,720,000 red blood cells per c.mm., 58,000 white corpuscles, haemoglobin 56 per cent. The differential count revealed polymorphonuclears 88 per cent.; lymphocytes 8 per cent., myelocytes 3 per cent., eosinophils 1 per cent. The second examination of the blood showed 3,748,000 red blood cells, 56,250 white corpuscles; with polymorphonuclears forming 86 per cent., myelocytes 3 per cent., lymphocytes 9 per cent., and eosinophils 1 per cent. Poikilocytosis was a well-marked feature. Biochemical investigations indicated a blood calcium figure of 8.6 mg. in 100 c.cm., and blood fragility was complete in 0.4 per cent. of saline; van den Bergh's test gave a direct negative and an indirect weak positive reaction. The blood pressure was 110 mm. systolic, and 70 mm. diastolic. The patient was submitted to a course of deep *x*-ray therapy, under which the leucocyte count came down to 7,800, and the haemoglobin to 42 per cent. The patient died after a fit on September 13th.

The necropsy showed marked enlargement of the anterior and posterior chains of the glands in the neck. There was a swelling in the middle line of the neck, which on incision was found to be an abscess of the size of an orange, with a well-defined wall; it contained yellow pus. There were a number of smaller glands in the axilla, which were discrete and slightly movable; a group of glands could be felt also in the groin. Obliterating pleural adhesions were present on the right side, while in the left pleural cavity there was an empyema pushing down the diaphragm and causing a pressure collapse of the base of the left lung, which was adherent above, completely shutting off the empyema. There was some oedema of the tissues of the superior mediastinum. A lump of matted glands formed a large swelling surrounding the bronchi and the aortic arch, filling up the shoulder girdle, and extending behind the heart. There was no infiltration of the pericardium. The left lung was oedematous at the apex, the base was collapsed; the pleura was thickened and adherent, shutting off the empyema. The tracheo-bronchial glands were enlarged and pigmented; they showed foci of caseation. The right lung showed pleural tubercles near the hilum suggestive of lymphatic spread. Microscopically, thickening of the pleura was found, and miliary tubercles were seen. The heart showed brown atrophy. In the liver there were a few miliary tubercles, underneath the capsule as well as inside the organ; there was also acute congestion. The spleen was not enlarged, but was smaller than normal; there were white opaque areas of variable size which, on microscopical examination, proved to be caseating and conglomerate tubercles, with well-developed giant cell systems and commencing caseation. There was marked fibrosis. Both kidneys contained pyaemic abscesses and a few retention cysts. The other organs were healthy, except that the peri-pancreatic glands were enlarged. The periosteum of the right clavicle was infiltrated, and the marrow of the bone itself was involved.

The glands on section presented those curious yellowish-white opaque flecks which resembled tuberculous caseous material, but were rather more firm, more opaque, and discrete; they stood out prominently from the surrounding tissue. Some glands showed a number of these tiny opaque flecks which were not fused together like tuberculous caseous material. Other glands showed marked enlargement, and on section no necrotic areas were found, but there were typical gelatinous areas with strands of fibrous tissue running into the gland from the capsule. There was some peri-adenitis in the intrathoracic group, but very little in the smaller glands.

Microscopically the glands that were uniformly enlarged showed well-marked fibrous transformation; here and there a few groups of lymphoid cells were seen, but the differentiation of the gland into lymph sinuses and follicles was entirely lost. There was, however, no diffuse endotheliosis, but well-marked fibrosis of the sclerosing type, with fully formed fibrous tissue. The lymphoid accumulations between these strands were found to be composed of a few endothelial cells, with rather pale large nuclei arranged in a cluster in the centre, so that the protoplasm formed only a scanty rim round them—a picture which Andrewes has defined as quite distinct from that of tuberculous lymphadenitis. The nuclei were mostly oval, with a ring of distinct nuclear membrane, and one or two dark chromatin nodes. Eosinophils were very scanty in the sclerosed glands, but numerous in the soft ones. The lymphoid cells were of the large and small lymphocytic type.

The presence of myelocytes in the blood is interesting and unusual. It will be remembered that the earlier authors have described cases of lymphadenoma with a myelocytic blood picture, and Cohnheim first applied to it the term "pseudo-leukaemia," assuming that it was a form in which the leukaemic blood picture was absent. Rolleston holds that the presence of leukaemic blood changes would now, with our modern accuracy of haematological methods, rule out a diagnosis of Hodgkin's disease. But in this undoubted case of Hodgkin's disease the presence of a few myelocytes indicates response of the bone marrow, showing that the process is not very far removed from a real leukaemic hyperplasia. It may be added that Fabian has recorded a few myelocytes in cases of Hodgkin's disease, but they were too few to estimate. The presence of myelocytes may indicate involvement of the bone marrow, since undoubted involvement of the clavicle was found in the case mentioned above.

The hyperleucocytosis of 56 per cent. is evidently a reaction to sepsis from the empyema and abscess in the gland. The polynuclear leucocytosis of Hodgkin's disease is both absolute and relative, but the counts seldom exceed 20,000.

The occurrence of an abscess in one of the glands in the neck is unusual, and raises the question whether these necrotic foci are the starting point of the abscesses. This, again, may suggest the view that lymphadenoma is a secondary infection—a view which is emphasized by Horder—an infection supervening on some previous chronic lymphadenitis.

With regard to the eosinophilia, Longcope holds that it is most common where there are necroses in the glands. Bunting, on the other hand, contends that eosinophils are low in the blood in the active stages of the disease, seeing that they all emigrate into the lymphatic glands, the destruction of the lymphocytes there apparently serving as a stimulus. In this case it is noticeable that necrosis in the glands was well marked, but the eosinophilia was slight.

OBSERVATIONS ON TWENTY-THREE CASES OF CARCINOMA OF THE BLADDER TREATED BY RADIUM.

BY

A. CLIFFORD MORSON, O.B.E., F.R.C.S.,

SURGEON TO ST. PETER'S HOSPITAL FOR URINARY DISEASES.

THE consensus of opinion on the Continent appears to be that malignant disease of the genito-urinary organs, apart from the penis, reacts unfavourably to radium treatment. In the majority of cases the method of surface application has been adopted in preference to what is termed the surgery of access.

Research on the treatment of bladder carcinoma by buried radium needles has been carried out by me at St. Peter's Hospital since 1925. Twenty-three cases of inoperable carcinoma have been so treated during this period, and kept under careful observation.

The figures which are given in this short communication might produce a misleading impression of the value of irradiation without a study of the clinical aspects of each case both before and after treatment. So ill were some of the patients when first examined that death appeared

imminent. In two cases blood transfusion had to be resorted to in order that the patients might be kept alive during the operation of suprapubic cystotomy. The bladder haemorrhage was controlled within a few hours of the onset of the radium exposure.

It is necessary to stress the point that all the twenty-three patients, before treatment was commenced, were profoundly ill from either sepsis or profuse haemorrhage.

Three of these patients died in hospital within one month of irradiation. The remainder, twenty, were discharged from hospital in fair health, with their suprapubic wounds firmly healed, at periods ranging from three to five weeks.

One patient survived three years, and one two years.

Two patients treated in 1927 are alive, one of whom shows no recurrence of the growth, the other writing to say he is in poor health. A third patient is dead.

The remaining fifteen cases have been treated during the year 1928. Five have died since discharge from hospital. Ten are in fair health, and continue under observation.

In all cases of carcinoma of the bladder haemorrhage can be controlled by irradiation. In the presence of severe cystitis the prognosis is always bad.

The suprapubic wounds, without exception, have healed rapidly. In those cases where sepsis has been absent both general and local conditions have improved for about six months after irradiation. Improvement after this period has not been maintained apart from one or two exceptional cases.

One case of carcinoma of the female urethra invading the bladder, treated twelve months ago, remains a clinical cure. Previous to treatment there was complete incontinence of urine. *Micturition is now normal.*

The radium technique which has been adopted is as follows.

First a suprapubic cystotomy is performed, and the extent of the growth determined by palpation. Five milligrams of the element, in platinum tubes 25 mm. in length and with a screenage of 0.5 mm., are then inserted 2 cm. apart into the periphery of the tumour on its mucous surface, and also on its external aspect. The tubes remain in position for twelve to twenty-four hours. Each tube is threaded with silkworm-gut, and at the termination of the period of exposure is easily withdrawn from the bladder through the suprapubic wound. The silkworm-gut is used in preference to silk on account of its strength, and less likelihood of being torn when pulled on.

The fact that improvement, both in the general state of health and also in the local condition, occurred, in practically all the cases is encouraging. Increase in weight in every patient was noted for six months after the radium exposure.

OVARIOTOMY FOR UNUSUALLY LARGE OVARIAN CYST IN A WOMAN OF 73: RECOVERY.

BY

WILLIAM EVERETT, M.B., F.R.C.S.ED.,

CARDIFF.

ATTENTION was drawn to the comparative rarity of the operation of ovariotomy in women over 70 years of age by Leslie Williams (see the *British Medical Journal* of April 13th, page 679), who cites two personal cases, bringing the total of recorded cases up to 155.

Very large ovarian cysts are not now often met with, for the simple reason that surgical facilities exist to-day for their removal before they attain to the size pictured in the textbooks of a generation ago. Now and again a case appears where the patient has been content to put up with things and live with her cyst, undismayed by its increasing size, even although advice for its surgical removal has been given. The following case is therefore recorded both on account of the rarity already mentioned and also because of the unusual size of the ovarian cyst removed.

The patient, who was 73 years of age, was seen by me on October 27th, 1927, in consultation with her family doctor, with a view to advising upon operation for an enormous swelling of the abdomen, thought to be caused by an ovarian cyst.

The patient was a woman of small stature, very cheerful and intelligent. She had had several children, and the menopause had occurred when she was about 50 years of age. When she was 65 she became conscious of her abdomen enlarging, but had decided not to worry about this misfortune until, eight years later, when she was 73, the swelling of the abdomen had become so great as to interfere seriously with her breathing and getting about. She then complained of abdominal and sciatic pains, fatigue and breathlessness upon exertion, palpitation, sleeplessness, constipation, and inability to hold her water.

She was lying upon her side in bed when I saw her, and when she lay upon her back she was unable to see the top of the bedrail at the foot of her bed. She was a little cyanotic, with dilated venules about the nose, was troubled with slight bronchitis, and had a small degree of oedema round the ankles. Her heart action was arrhythmic and the sounds were feeble, although the valves were competent.

Examination of the abdomen revealed an enormous dull swelling rising from the pelvis and filling the whole abdomen as far as the xiphisternum, with changing areas of resonance to percussion on either flank. The fluid thrill was easily elicited. A diagnosis of large ovarian cyst was made, and preliminary puncture and drainage was advised, to be followed at a later date by ovariotomy.

Paracentesis was performed on October 29th, 1927. On this date an area midway between the umbilicus—which was protruded—and the pubic symphysis was anaesthetized with 1 per cent. novocain, and the cyst punctured by a large trocar and cannula. A long rubber tube was then attached to the cannula and led beneath the bed into a 10-gallon zinc wash-bath, and the fluid contents, which resembled pea-soup, were thus slowly removed. The joy of the old lady increased as her abdomen diminished, and her happiness seemed complete when she raised her head and saw her toes! It was considered best to withdraw the cannula without pressing upon the cyst, in view of possible leakage when the flow had almost ceased. The 10-gallon bath was approximately half full, and upon later measurement the amount of fluid totalled nearly 40 pints.

Two weeks later she came into a nursing home, and on November 17th was operated upon for the removal of the sac. Ovariotomy was performed under chloroform and ether, attempts to introduce the needle for spinal anaesthesia having failed. Slight adhesions were encountered, but after bringing the cyst to the surface of the wound and withdrawing about ten pints of fluid which had again collected, the huge sac slipped out of the abdomen with gentle traction. Blood vessels the size of adult fingers spread over its surface from the pedicle, which was situated upon the right side. The pedicle was securely ligated and the cyst removed, the operation giving rise to no difficulty and being completed in twenty-five minutes.

The specimen was an ovarian cystadenoma, with smooth, tough, and evenly thick walls about three-eighths of an inch thick, except at the base, where there were septal remains.

The patient made an uninterrupted recovery, and left the nursing home at the end of twenty-one days, and now, at 75, enjoys very good health.

I regret that a photograph was not taken before operation, and that the weight of the cyst and its contents was not ascertained by recording the weight of the patient before paracentesis and after ovariotomy.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TWO CASES OF OVARIOTOMY IN WOMEN AGED 84 AND 77 RESPECTIVELY.

IN view of the article by Mr. Leslie Williams in the *Journal* of April 13th, I should like to record the following two cases.

CASE I.

Mrs. X., aged 84, a patient of Dr. Mitchell of Guildford, was, on May 1st, 1918, operated on for a large ovarian cyst, the size of a full-term pregnancy. The tumour was a huge, simple cyst of the right ovary, and was removed entire without previous tapping. The patient made an uninterrupted recovery and has remained well ever since. She is now 95 years of age and in good health.

CASE II.

Miss Y., aged 77, was a patient of Dr Cliff-Hodges of Godalming. She was a very frail old lady, crouched, and bent in her bed, and was toothless except for two old stumps. She had been an invalid for years, but had lately suffered from intestinal obstruction, which at the time of my visit had been partially relieved by enemata, and the vomiting had ceased. Her temperature was 100°, and her pulse was rapid and feeble. The abdomen was filled with a huge, irregular, tender solid tumour, which had recently been wedged into the pelvis; but Dr. Cliff-Hodges had partially dislodged it and thus to some extent relieved

the situation. She was an exceedingly bad operative risk, apart from the fact that the tumour was likely to prove malignant and inoperable. She was therefore advised that operation would be very risky and that it would be better, seeing that her obstruction had been relieved, to continue with palliative treatment. She, however, took a different view, and said that she could bear the pain no longer, and insisted on operation, whatever the risk might be.

The operation was performed on June 13th, 1928. There was much free fluid in the abdomen; the tumour was greenish-black in colour and loosely adherent to the bowels; the adhesions were separated and the tumour was found to be a large fibroid springing from the left broad ligament and twisted two complete turns on its short pedicle. The tumour was removed. A solid tumour of the right ovary, the size of an orange, was also removed.

The patient made a wonderful recovery from the operation and enjoyed very good health, and was able to get about for seven months. Since then she has been in failing health, and is now reported to be dying, with symptoms of intestinal obstruction.

Unfortunately, through some misunderstanding, the specimens were not submitted to the pathologist.

H. B. BUTLER, F.R.C.S.Ed.,
Surgeon, Royal Surrey County Hospital.

Guildford.

ELEPHANTIASIS NEUROMATOSA.

WITH reference to the case of elephantiasis neuromatosa reported in your issue of March 30th, I beg to forward photographs of a case I came across shortly before returning home from India this year.

I was travelling from Poona to Dehra Dun, and my train had been held up for some time at a halting place just outside the station of Dholpur, when the unfortunate subject of the photograph appeared. As the train was already signalled to proceed I employed the few moments at my disposal in exposing two films from the carriage door.

The affection was apparently limited to the right shoulder, arm, and hand—it is unlikely that any other such source of income would have been hidden, if present—otherwise the subject appeared to be no different from his mendicant confreres. It is interesting to note how the forearm has escaped in comparison with the rest of the limb, and to compare the girth of the calves of the legs with that of the two massive fingers; presumably these are the index and middle fingers, with the ring finger hidden.

The affected hand was carried on the top of the head during "business hours," partly, no doubt, on account of the weight, and partly for the more advantageous display of the abnormality; on the departure of the train, however, it was allowed to fall to the side. The presence of voluntary movement of the joints may be seen by comparing the two views.

On my return journey, a few days later, I was disappointed to find the lad absent from his post, and my endeavours to trace him, for the purpose of fuller investigation, proved fruitless. It is hoped, however, that the photographs alone may be of interest, and it is extremely doubtful whether, if it had been advised, he would have consented to the loss of the limb, the value of which may be gauged by the weighty condition of the small pocket on his shirt, which pocket contained, presumably, the takings from that one train only.

R. BOULTON MYLES,
Major R.A.M.C.

Radiological Department, Royal Herbert Hospital, Woolwich.

CONGENITAL ABSENCE OF THE STERNO-COSTAL PORTION OF THE PECTORALIS MAJOR MUSCLE.

CONGENITAL absence of the pectoralis major muscle is rare enough to lend interest to the case shown in the accompanying photograph. The patient is a boy, aged 7, with absence of the greater part of the sterno-costal portion of the pectoralis major muscle of the *left* side. The sterno-clavicular portion of the muscle and the portion taking its origin from the first and second ribs are present, the lower border of the muscle being in line with the upper border of the second rib when the arm is extended outwards. The digitations of the serratus magnus muscle are by no means marked, but this condition is probably due to insufficient development. An article which appeared in the *British Medical Journal* on July 10th, 1926 (p. 59), records a similar case and is furnished with a useful bibliography.

A. G. NEWELL, M.D., D.P.H.

St. Leonards-on-Sea.

A CASE OF PSEUDO-HERMAPHRODITISM.

IT is unusual for it to be discovered, as in the case reported below, that a woman has been brought up as a man; more often the position is reversed—a man is brought up as a woman. Economically, it was a serious decision to have to make, but there appeared to be no other course, and the result has been to give comfort to the patient where previously there was distress.

In male attire, the patient gave her age as 17 years. As stated above, she had been brought up and educated as a male, in humble circumstances in the country. Latterly she had earned her living as the boy employed to assist the driver of a wagon for the distribution of petrol. To show that she had done her work well it may be recorded that on one occasion she won a prize at a show for the best turned out lorry; on another occasion she was left, snow-bound, in charge of the wagon on a lonely moor for three nights, while the driver went to seek help. That she was a woman was not suspected. She found it inconvenient to have to sit to make water, but it was not until she began to menstruate at the age of 17 that she sought the aid of the district nurse.

Her doctor sent her to see me because he considered that she was a woman, and that it would be necessary to stop her from living as a man. The skin of the face was smooth, and the voice was that of a woman. The figure was boyish. The breasts were those of a woman and well formed. The pubic hair was of the female distribution. The clitoris was large, and of the size of the penis of a baby. The labia majora were fused in a median raphé, giving to the parts an appearance of a scrotum devoid of testes. At the anterior end of the bag was an orifice, through which urine was passed with difficulty.

It was decided that since, physically and psychologically, the patient was more woman than man, it would be inadvisable to permit her to remain in male attire to continue living as a man. Accordingly, having entered hospital in male attire, she was provided with female bed attire and admitted as a woman to a female ward. Her Christian name was changed to the nearest feminine equivalent, but no change could be made in the particulars of the birth registration.

Under general anaesthesia the median raphé was divided, and the edges were sutured to form labia. The urethra opened high up in a tiny vagina, which admitted the end of the little finger. In the vault was a rudimentary cervix. By combined rectal and abdominal examination a rudimentary uterus was palpated, and small ovaries, as they were taken to be.

Since discharge from hospital the patient has been employed as a female domestic servant. She has menstruated regularly for three days at a time. She says that she is much happier living as a woman. Not uncomely, she is fond of wearing becoming clothes, and looks and behaves like a woman.

JAMES RIDDELL, M.D., F.R.C.S.Ed.,
Honorary Assistant Surgeon, South Devon and East Cornwall Hospital, Plymouth.

Reviews.

SURGICAL DIAGNOSIS.

A Text-Book of Surgical Diagnosis,[1] edited by Mr. A. J. WALTON with the assistance of thirty-six collaborators, is written for both the general practitioner and the surgeon, and aims at improving bedside diagnosis rather than stimulating test-tube research. It includes, however, a well-balanced chapter on the diagnostic value of laboratory methods, in which Dr. Panton describes the tests in use and assesses their significance. As in most books by a number of separate contributors, there is some overlapping, and occasionally it happens—for example, in the passages dealing with rodent ulcer—that when several authors treat of the same disease they do not say the same thing. The contributors, to all of whom Mr. Walton states he gave a free hand, approach their subject in various ways, some through diseases, some through symptoms, others through pathology. The majority of contributors have taken the first way, but the second has much to commend it. To use a book like this for reference it is often necessary to make a diagnosis before finding the section in which the method of diagnosis is described. It is difficult to see how the variety of approaches could have been avoided without altering the plan of the work and converting it into an index of symptoms. None the less, more might have been done on the lines of Chapter xxiv, in which Messrs. Gordon-Taylor and Hudson discuss lesions of the intestines by way of the symptoms they produce.

Most of the chapters are excellent, and will repay careful study. Mr. Harry Platt writes admirably on injuries and diseases of nerves, with just the right mixture of anatomy, physiology, well-chosen diagrams, and bibliography. Spinal cord lesions are successfully handled by Mr. Jefferson, the brain and skull by Drs. Riddoch and Russell Brain. Mr. Lockhart-Mummery's twenty-two pages on the rectum and anus contain the wisdom of a ripe experience. His remarks on history-taking and the examination of the patient are particularly interesting. He does not mention polyp as a cause of rectal prolapse, and dismisses cancer of the rectum in a page and a half, but his article is none the less admirable. Recent developments find a place, and there are *x*-ray photographs showing the use of lipiodol in the diagnosis of thoracic and spinal conditions, and of sodium tetraiodophenolphthalein in gall-bladder disease. Much of the work has devolved upon the editor, and he is responsible for seven of the fifty-two chapters. He has mainly concerned himself with the abdomen, but chapters in this section have also been contributed by Messrs. Cope, Wilkie, Gordon-Taylor, and Perrin. The book covers all the ordinary special subjects, and even includes separate chapters on tropical diseases, gynaecology, and glanders. Mr. Victor Bonney, Mr. Sydney Macdonald, and Mr. Norman Patterson write on their own specialties, and bones and joints are considered by Messrs. Fairbank, Bankart, Driberg, Milne, and Timbrell Fisher.

Within its self-imposed limits the book is sound and authoritative. On the whole it is well produced, but there is only one index to the two volumes and misprints are rather frequent. The illustrations, of which there are 570, all bear on the art of diagnosis.

GENERAL ANAESTHESIA.

IT is interesting to compare two standard textbooks on anaesthesia, one originating in this country, the other of transatlantic origin, and the opportunity has arisen by the recent appearance of STUART ROSS and FAIRLIE'S *Handbook of Anaesthetics*[2] and FLAGG'S *Art of Anaesthesia*,[3] the former in its third, the latter in its fourth edition.

Complete comparison is impossible, since the British volume is much smaller than the American, and naturally does not go so deeply into the subject; but allowing for this fact, one is able to make some comparison between the teaching in the two countries. On the whole, there appears to be a tendency in America to use elaborate apparatus and dosimetric methods to a larger extent than in this country. In England private surgical practice is conducted mostly in nursing homes of small capacity and in private houses. The anaesthetist is therefore compelled to work with apparatus that is easily carried about, and most apparatus used with dosimetric methods is bulky, heavy, delicate, and transportable with difficulty. In America, on the other hand, most surgical operations are performed in large hospitals and clinics, and apparatus need not be moved about to anything like the same extent. The student in this country has therefore to be instructed in methods and with apparatus of the simpler type, much of his teaching necessitating only the use of "the rag and bottle." This method, however, is absolutely necessary to the beginner, and no one can hope to become a specialist in the art of anaesthesia without proper grounding in the simpler methods of administering the various anaesthetics.

In both volumes a prominent place is given to the value of nitrous oxide-oxygen anaesthesia. It would appear, however, that some American surgeons are willing to work under conditions of semi-relaxation of the abdominal muscles which would draw protests from most British surgeons, and it is at least questionable whether the risks of ether anaesthesia are greater than those of nitrous oxide-oxygen anaesthesia pushed to the extreme limit. No doubt in the hands of experts a very great deal can be done with nitrous oxide-oxygen alone, but many operations have to be carried out with the aid of average anaesthetists who do not devote a large portion of their time to anaesthetic work, and in their hands ether is safer than nitrous oxide-oxygen pushed to the limit. Both volumes emphasize the dangers of chloroform, but agree that it has its uses in special cases. The use of ethylene is described in both volumes, and Flagg's account stresses the risks of explosion in the presence of any naked flame, electric spark, or even static sparks, when the drug is used with oxygen. On the whole both authorities agree that ethylene has a definite value in selected cases, and that it should only be used where the operation is to be of short duration. Intratracheal methods of administration are described in both volumes. There is not much difference in the methods or apparatus advocated by the two schools. As regards preliminary medication with drugs, such as atropine and morphine, the teaching of both schools is much the same, though the British authors condemn without reservation the use of morphine preliminary to the administration of chloroform. Local and regional anaesthesia are dealt with in both volumes somewhat briefly, but no mention of sacral anaesthesia is made in the American volume. It is impossible adequately to deal with local and regional anaesthesia in a short space, and in our opinion students should be referred to the larger textbooks for the minutiae of technique. Neither volume mentions the technique of local and regional anaesthesia for operations on the teeth.

The physiology of anaesthesia, shock, anoxaemia, etc., is well explained in each of these books, and due consideration is given to the preparation of the patient. Curiously enough, synergistic analgesia is mentioned in the English but not in the American volume, though the method is used mainly in America. The illustrations in both volumes are well chosen, but naturally the American volume, being larger, has many more. In our opinion both may be recommended to the student, the British one to the beginner as inculcating first principles, the other to the more advanced student as representing the teaching of the American school.

KAUFMANN'S PATHOLOGICAL ANATOMY.

KAUFMANN'S Special Pathological Anatomy, a translation[4] of which has been prepared by Dr. STANLEY REIMANN, director of the Research Institute of the Lankenau Hospital, Philadelphia, is one of the best known and most widely valued works on that subject. It was, apparently, intended primarily as a textbook for students, but from the comprehensive treatment of the subject, the inclusion of every type of lesion revealed by an exhaustive study of the literature, and from the author's concise and orderly exposition, the book has obtained a world-wide reputation as a work of reference for all who are interested in pathological anatomy. Its classified bibliography alone, occupying 225 large pages of closely printed references, is in itself a work of great value to those requiring information on the history and recent advances in any particular branch of the subject. The original, being in German, is probably not familiar to many English readers; Dr. Reimann's translation will now bring it within the reach of all. The translation appears to adhere closely to the original text, and Dr. Reimann may be congratulated on the completion of what must have been an arduous task. The two volumes of the eighth German edition have been expanded into three volumes, chiefly through the adoption of one uniform type, the small type extensively used in the original being dispensed with. The inclusion of a large number of new illustrations also consumes considerable space; these are all good, and improve the work, although no criticism is to be made of Kaufmann's figures, which have the special merit of having been drawn by himself. The translator has thought it desirable to add paragraphs on some recent advances. Notes on subacute bacterial endocarditis, on the effects of short-circuiting the blood stream from an artery to a vein, and on tularaemia, have been inserted. Several pages are devoted to a discussion of the complicated histological changes met with in goitre; the translator considers that it would simplify matters to regard the enlargement as occurring in stages—a stage of hypertrophy or change to the cylindrical form of cell, of hyperplasia or cell proliferation with reduction of the lumina, and a colloid stage in which the cells undergo atrophy leaving larger or smaller colloid vesicles. Combinations of these stages would account for the complex appearances. Reference is made to the extreme difficulty experienced in some cases in making a histological diagnosis of carcinoma of the thyroid; it would seem that in some instances the only certain criterion of malignancy may be the invasion of blood vessels and tumour thrombosis, and that all other microscopical pictures, no matter how atypical, may be those of a benign growth. Mention is made of the recent explanation of the greater liability of the right lobe of the liver to amoebic abscesses; it is supposed that the streams from the splenic and superior mesenteric veins retain their relative positions, without intermingling, in passing through the portal vein, "analogous to the condition of the Mississippi below the point where it is joined by the Missouri." This American touch is exhibited to some extent also in the general orthography of the work; such forms as fetus, edema, and amebic are familiar to, and to some extent adopted by, English writers, but it is doubtful whether divertículi and diverticulae will prove acceptable as forms of the plural of diverticulum. Mallory's view is mentioned, that haemachromatosis and bronzed diabetes are caused by copper-poisoning, from metal derived from cooking utensils; and a note on scarlet fever expresses some doubt in regard to a streptococcus as the cause of the disease, and to the skin test, antitoxin, and immunization. Paragraphs added are in every case noted as additions, and, not being numerous, in no way alter the general character of the work. It will be noticed that the title differs from that of the original, but the latter would seem to be the more appropriate, since the work is essentially one on special pathological anatomy. The three handsome volumes reflect great credit upon the publishers.

[4] *Pathology for Students and Practitioners.* By Dr. Edward Kaufmann. Translated by Stanley P. Reimann, M.D. In three volumes. London: H. K. Lewis and Co., Ltd. 1929. (Sup. roy. 8vo, pp. 2452 + lxii; 1072 figures. £6 6s. net the three volumes.)

PROTOZOOLOGY.

DR. J. G. THOMSON and Dr. A. ROBERTSON, director and lecturer respectively in the department of protozoology of the London School of Hygiene and Tropical Medicine, have written a book on *Protozoology*[5] which is admirably adapted to the needs of doctors engaged in the practice of tropical medicine and students preparing for examination in this subject. The authors present brief and clear descriptions of the protozoal parasites of man, together with an account of the pathology of the lesions they produce. The volume opens with a general introduction on the structure and nature of the cell, and on the classification of the protozoa generally. Descriptions follow of the malarial parasites of man, coccidia, amoebae, the human flagellates, including leishmania and trypanosomes, and the ciliates. In each case the parasite, its biology, transmission, and host reactions, are carefully and clearly explained, the authors holding that an accurate conception of the parasitic nature of an organism is attainable only by reference to the tissue and other reactions of the host. Chapters are included on examination of the blood and faeces and the interpretation of such examinations, on various organisms of a vegetable or doubtful nature (for example, spirochaetes and rhinosporidium), on parasites in other mammals and in birds, and on technique, derivations, and definitions. Several good books on protozoology have appeared in English within the past few years, but most of them have been too large for the student. The present volume, while making no pretence at being exhaustive or encyclopaedic, is probably the most suitable that has yet been published for the ordinary medical man in the tropics. It contains all the information he is likely to require in everyday practice, and, in addition, descriptions of the pathology of the protozoal diseases which he could otherwise obtain only from a study of a number of large textbooks and monographs. The volume is profusely illustrated with drawings and photomicrographs, and with four excellent coloured plates.

[5] *Protozoology.* By John Gordon Thomson, M.B., Ch.B., and Andrew Robertson, M.B., Ch.B. London: Baillière, Tindall and Cox. 1929. (Cr. 4to, pp. xvi + 376; 220 figures, 4 plates. 30s. net.)

THE CONCISE OXFORD DICTIONARY.

IT is now nearly eighteen years since we first commended to the notice of our readers the *Concise Oxford Dictionary of Current English*,[6] prepared for everyday purposes by H. W. and F. G. FOWLER, and founded by them on the principles of the great *Oxford English Dictionary*, at that time four-fifths completed. Distinguishing features of this work, whose merits have been so widely recognized, were the large amount of space given to common words and colloquialisms, the copious use of illustrative sentences, and the brief treatment of uncommon words or those better fitted for the encyclopaedia than the dictionary. In compiling it the authors kept closely to the idea that a dictionary must be concerned primarily with words and phrases as such, and not, except so far as is needed to ensure their right treatment in speech, with the things those words and phrases stand for. The object they set before themselves was to present as vivid a picture as the small dictionary could be made to give of the English that was being spoken and written at the time. By general consent the outcome of their labours was, for its size, by far the best English dictionary ever produced—full, accurate, informative, and judicious in its choice of technical terms. In the intervening years the game of word-coining and phrase-making went on apace, so that many additions and some alterations became necessary if the book was to preserve its character as a dictionary of current English. Francis George Fowler died in 1918, and the work of revision has been carried on by his brother. As the surviving author remarks in his preface, a living language does not remain unchanged through twenty years and a great war: "Our picture has needed, and received, a good deal of retouching

[6] *The Concise Oxford Dictionary of Current English.* Adapted by H. W. Fowler and F. G. Fowler from the *Oxford Dictionary*. New edition; revised by H. W. Fowler. Oxford: The Clarendon Press. 1929. (Cr. 8vo, pp. 1434 + xvi. 7s. 6d net; thin paper 10s. 6d.)

before being again exhibited in public, and its owners, the Clarendon Press, have thought it worthy of a slightly larger and more handsome frame." Thus, while the aims and methods of the dictionary remain what they were, detailed changes in the text are very numerous, and the general format has been modified in several respects. Some 400 pages have been added, but the columns are narrower, there are fewer lines to the page, and a pleasanter and more legible type is used. The short list of those to whom Mr. H. W. Fowler makes acknowledgement for special help in the preparation of the second edition includes the name of our late Editor. We know that Sir Dawson Williams's appreciation of the "*C.O.D.*" survived the test of sixteen years' daily use, and a cursory examination of the new edition assures us that it would have met with his critical approval. A fresh lease of popularity can be predicted for this admirable work of reference.

BOOKS FOR NURSES.

MR. COMYNS BERKELEY'S well-known book on *Gynaecology for Nurses and Gynaecological Nursing*,[1] now in its fifth edition, is a complete and well-written volume that has proved of the greatest service to members of the nursing profession ever since its first edition appeared nearly twenty years ago. It is divided into six parts. The first five of these deal with the anatomy and physiology of the female organs, with pregnancy, with parturition, and with the diseases of the reproductive tract. The sixth part, extending to some 160 pages, is devoted to gynaecological nursing. The book is thoroughly up to date, well illustrated, and well turned out. It may be warmly recommended to the attention of all nurses in search of instruction in the subjects with which it deals. In the volume by Miss L. OAKES, entitled *Essentials of Gynaecology for Nurses*,[2] is set out a brief course of questions and answers for examination candidates that might well be used as a test of their knowledge by nurses who have been through Mr. Comyns Berkeley's more elaborate and informative text-book. Miss Oakes has written her book primarily for the general nurse, and chiefly as an aid in the preparation for the State examinations. It takes the form of questions and answers throughout; and, in addition, nine test papers are set, the answers to the questions in them being given at the end of the volume. The book is clearly written, and should prove of real value to nurses studying gynaecology. A further example of the application of the method of question and answer in the teaching of nurses is provided by an American volume from the School of Nursing at St. John's Hospital, Cleveland, Ohio: *Questions and Answers for Nurses*,[3] by Miss I. V. KELLEY. The first few pages of this book set out the recent improvements in the style and method of examinations that take the form of what are described as "objective (new type) examination questions," of the "recall type," in which the examinee may complete a skeleton statement, or make a pertinent statement about a word presented to her, and of the "recognition type." Here the examinee is offered complex statements which must be identified as true or false; or must choose the correct answer from the number offered to her; or must set the correct answer side by side with the appropriate question (much as one may have to do in the more elaborate acrostics or cross-word puzzles); or must identify the corresponding members in the analogies that may be drawn in anatomy, bacteriology, and so forth. The bulk of the volume is more commonplace, and is devoted to the "essay (old type) examination questions" of the old-fashioned sort. This is designed to enable a nurse to review all the subjects in the curriculum of the various schools of nursing, and appears to fulfil its purpose in a tolerably satisfactory fashion. The third edition of Dr. H. C. RUTHERFORD DARLING'S *Surgical Nursing and After-Treatment*[10] gives an excellent account of the subject with which it deals, and is intended for the use not of nurses only, but also for students and dressers and the junior members of the medical profession. The first half of the book deals with general surgical nursing, the second half with regional surgical nursing. There is a great deal of information in Dr. Darling's book, which is well written and adequately illustrated; we wish it the success it deserves. *Nutrition in Health and Disease for Nurses*,[11] by Drs. LENNA F. COOPER and EDITH M. BARBER and Miss HELEN S. MITCHELL, gives a full account of the principles of nutrition and of the details of diet in disease. It is divided into four parts, treating respectively of the principles of nutrition, the selection of foods, diet in disease, and cooking for the sick and convalescent, at approximately equal length. There is a great amount of up-to-date information in this volume, and it should appeal to a far wider audience than the nursing profession; it may be recommended also to physiologists, medical men, and all who are interested in the principles and details of scientific feeding as it is understood in America. The fourth edition of Dr. RUTHERFORD DARLING'S *Elementary Hygiene for Nurses*[12] gives a soundly written account of the subject that may well be placed in the hands of anyone seeking an introduction to the principles of hygiene in house and town. It has a number of excellent illustrations, and the author has adopted what may be called English standards in writing it. *Applied Bacteriology for Nurses*,[13] by JEAN WHITE, endeavours to supply nurses with such practical knowledge of bacteriology as may be of service to them in their daily round, and outlines for them a scheme of laboratory work. It should be useful to such nurses as have the opportunity to study the subject in any but a superficial manner. Dr. I. J. SANDS's book on *Nervous and Mental Diseases for Nurses*[14] gives a short and sufficient account of the various forms of mental disease and neurological disorders that nurses may meet with in their patients, and sets out the ways in which the nurse may help the medical man in their treatment. It can be recommended to those readers for whom it is designed.

NOTES ON BOOKS.

THE *Manual of Otology*[15] by Dr. GORHAM BACON, with whom Dr. T. L. SAUNDERS is now associated in the preparation of the eighth edition, is perhaps less known and appreciated in this country than it deserves. The number of editions issued is sufficient evidence of its success in America. It is a book which presents the study of otology in a sane, balanced, and practical fashion. The manner in which it is written, and the frequent references to first-hand experience, stamp it with the personality of the authors, who prove themselves free from fads and to be sound guides in the pathology and the surgery of the ear. The arrangement of the different sections and the general approach to the subject are in a conventional style, but the book has been brought thoroughly up to date in all points concerning the labyrinth and intracranial extensions of aural disease by the additions made by Dr. Saunders. We recommend this book warmly as an excellent manual for house-surgeons, clinical assistants, and practitioners.

The first volume of the twenty-eighth edition of the late Professor Strumpell's textbook of pathology and therapeutics[16] has now appeared. Professor C. SEYFARTH, who is responsible for the revision, contributes a short preface. New subjects dealt with in this edition include undulant and dengue fevers, abscesses of the lung, and ulcerative colitis. The new edition is conspicuous for its many and good illustrations, and for the excellence of its subject-matter.

Dr. F. F. MARTÍNEZ's work[17] on intestinal occlusion, which, as we learn from the preface, is not intended for beginners but for experienced practitioners, is divided into three parts, dealing respectively with the diagnosis, etiology, and treatment of intestinal obstruction. A list of the writer's publications is appended.

[15] *A Manual of Otology.* By Gorham Bacon, M.D., F.A.C.S., and Truman Laurence Saunders, M.D., F.A.C.S. Eighth edition, thoroughly revised. Philadelphia: Lea and Febiger. 1928. (Post 8vo, pp. vi + 575; 120 figures, 2 plates. 4.50 dollars.)
[16] *Strumpell-Seyfarth Lehrbuch der Speziellen Pathologie und Therapie der inneren Krankheiten.* Achtundzwanzigste, neu bearbeitete Auflage. Erster Band. Von Dr med. et Phil. C. Seyfarth. Leipzig: F. C. W. Vogel. 1929. (6¾ × 9¾, pp. xiii + 880; 177 figures, 12 plates. 34.25.)
[17] *El Problema de la Oclusión Intestinal.* Fidel Fernández Martínez. Madrid: Javier Morata. 1928. (5½ × 8¼, pp. 137; 39 figures.)

For the benefit of the layman Dr. IAN THOMSON has "potted" medicine into a booklet of little more than 100 pages, under the title *Good Health*.[18] He combines the art of compression with the faculty of clear exposition; so well, indeed, that Sir ARTHUR KEITH seems justified in saying in his preface that the mantle of Professor Arthur Thomson has fallen upon his son. Perhaps the layman will find difficulty in digesting the five-page digest of hormones; and a glossary of medical terms might be useful as an adjuvant to some of the potions of knowledge; but there is nothing deleterious in the ingredients, nor anything that need produce nightmare in the most neurotic of readers.

The ninth volume issued by *The Medical Department of the United States Army in the World War*[19] is devoted to communicable and other diseases. The diseases discussed include the enteric group, inflammatory diseases of the respiratory tract, tuberculosis, cerebro-spinal meningitis, encephalitis lethargica, anthrax, diphtheria, venereal diseases, the diarrhoeal group of diseases, the acute exanthemata, mumps, infectious jaundice, typhus, trench fever, Vincent's disease, malarial fevers, diseases caused by intestinal parasites, diseases of the skin, and neuro-circulatory asthenia. The text is illustrated by numerous tables of the incidence, mortality, and complications of the various diseases. A list of references, mainly to American publications, is appended to each chapter.

We have received a copy of Dr. GABRIEL LANGFELDT's prize essay[20] on the clinical examination of the visceral nervous system. It contains a criticism of the various tests in common use, such as the intravenous adrenaline test, the pilocarpine reaction, the atropine reaction, the oculo-cardiac reflex, and the cilio-spinal reflex. The Norwegian text is followed by summaries in German and English.

Under the auspices of the well-known French journal *La Presse Médicale*, a pamphlet[21] on medical education and registration in France has been compiled for the use of those interested, whether in France or other countries. It contains detailed information about the educational facilities in Paris and some general notes about those in the provinces.

A booklet[22] describing spas in the centre of France has been prepared incorporating descriptions by several authors and a preface by Professor CARNOT. A brief account of each place is given, with notes of the pathological conditions for which the waters are specially recommended. The booklet will be of considerable assistance to those who wish to know the therapeutic possibilities in that neighbourhood.

PREPARATIONS AND APPLIANCES.

VITAMINS IN MARGARINE.

MESSRS. LEVER BROTHERS have drawn our attention to the results of tests on the vitamin content of certain of their margarines that have been carried out at two independent laboratories in this country. The margarines tested were special brands which had been activated by the addition of vitamin concentrates.

The manufacture of a margarine with an adequate vitamin content is a matter of considerable economic importance, for, until recently, animal fats have been the chief source of vitamins A and D, and the relatively high price of such fats has been an important factor in causing deficiency in these vitamins in the diet of the children of the poorer classes. The tests on margarine made by Dr. Katherine Coward have already been published (*Lancet*, October 6th, 1928, p. 726). She concluded that the particular brands of margarine that she tested were equal to the best summer butter in their vitamin A and D content, and that they were superior to many samples of butter tested.

Messrs. Lever Brothers have submitted to us the results of a second series of tests carried out in another laboratory. These show that the vitamin concentrates used in manufacture have a satisfactory vitamin content, and also confirm Dr. Coward's finding that the finished margarine has a vitamin content equal to that of good butter.

BIRTHDAY HONOURS.

THE Honours List issued on June 3rd, on the occasion of His Majesty's birthday, includes the names of the following members of the medical profession.

Order of Merit.

ROBERT BRIDGES, M.A., M.B., D.Litt., LL.D., F.R.C.P., Poet Laureate. In recognition of his eminent position in the world of literature.

Privy Councillors.

BERTRAND EDWARD, BARON DAWSON OF PENN, G.C.V.O., K.C.B., K.C.M.G., M.D., F.R.C.P., Physician in Ordinary to His Majesty the King.

The Hon. EARLE CHRISTMAS GRAFTON PAGE, M.B., Ch.M., Treasurer of the Commonwealth of Australia.

G.C.V.O.

Sir HUMPHRY DAVY ROLLESTON, Bart., K.C.B., M.D., F.R.C.P., Physician in Ordinary to His Majesty the King; Regius Professor of Physic in the University of Cambridge.

Baronets.

Sir EDWARD FARQUHAR BUZZARD, K.C.V.O., M.D., F.R.C.P., Physician Extraordinary to His Majesty the King; Regius Professor of Medicine in the University of Oxford.

Sir HUGH MALLINSON RIGBY, K.C.V.O., M.S., F.R.C.S., Serjeant Surgeon to His Majesty the King.

K.C.B. (Civil).

Sir FREDERICK STANLEY HEWETT, K.C.V.O., K.B.E., M.D., Surgeon to His Majesty the King and Surgeon Apothecary to His Majesty's Household.

K.C.V.O.

FRANCIS EDWARD SHIPWAY, M.D., Senior Honorary Anaesthetist to Guy's Hospital.

K.B.E. (Civil).

RICHARD RAWDON STAWELL, M.D., President of the Melbourne Hospital; for services to the Commonwealth of Australia.

Major-General THOMAS HENRY SYMONS, C.S.I., O.B.E., Honorary Surgeon to His Majesty the King; Director-General, I.M.S.

Knights Bachelor.

Professor WILLIAM COLIN MACKENZIE, M.D., F.R.S., Director of the National Museum of Australian Zoology.

ROBERT STANTON WOODS, M.D., M.R.C.P., Physician in charge of the Departments of Physiotherapy and Electrotherapy, London Hospital.

C.B. (Military).

Surgeon Rear-Admiral HENRY CADMAN WHITESIDE, M.R.C.S., L.R.C.P.

Major-General HAROLD PERCY WALLER BARROW, C.M.G., D.S.O., O.B.E., K.H.S. (late R.A.M.C.), Director of Hygiene, the War Office.

C.B. (Civil).

MAURICE ALAN CASSIDY, M.D., F.R.C.P., Chief Medical Officer of the Metropolitan Police.

C.M.G.

WILLIAM JAMES DEACON INNES, M.R.C.S., L.R.C.P., West African Medical Staff, Director of Medical and Sanitary Services, Gold Coast.

OLIVER FRANCIS HAYNES ATKEY, M.B., F.R.C.S., Director of the Sudan Medical Service.

C.I.E.

Major-General RICHARD WILLIAM ANTHONY, I.M.S., Surgeon General with the Government of Bombay.

CHARLES ALBERT BENTLEY, M.B., C.M., Director of Public Health, Bengal.

C.V.O.

HAROLD KINGSTON GRAHAM HODGSON, M.B., B.S., Radiologist to King's College Hospital.

FRANK DUTCH HOWITT, M.D., M.R.C.P., Physician in charge of Physiotherapy Department, Prince of Wales's General Hospital.

LIONEL ERNEST HOWARD WHITBY, *M.C.*, M.D., M.R.C.P., Assistant Pathologist, Middlesex Hospital.

M.V.O.

EDWARDS CHARLES DODDS, M.D., M.R.C.P., Professor of Biochemistry in the University of London.

C.B.E. (Military).

Colonel A. H. SAFFORD, V.H.S. (late R.A.M.C.), Assistant Director of Medical Services, Baluchistan District, India.

C.B.E. (Civil).

DONALD MACKENZIE MACRAE, M.D., Principal Medical Officer, Bechuanaland Protectorate.

Lieut.-Colonel JOHN WILLIAM WATSON, C.I.E., I.M.S., Civil Surgeon, Ajmer, and Chief Medical Officer, Rajputana and Ajmer-Merwara.

O.B.E. (Military).

Surgeon Commander FRANK LEWIS SMITH, R.N.
Major DOUGLAS GORDON CHEYNE, *M.C.*, M.D., R.A.M.C., Deputy Assistant Director of Hygiene, China Command.
Captain PETER FIFE ATCHINACHIE GRANT, M.B., I.M.S.
Major JOHN CLERK PYPER, M.B., I.M.S., late Medical Officer, Equitation School, Saugor, India.
Squadron Leader (Hon. Wing Commander) EDGAR HUNTLEY, M.B., B.S., R.A.F.

O.B.E. (Civil).

ALEXANDER SANDISON, M.B., Principal Medical Officer, Ministry of Pensions.
Major JAMSHEDJI NUSSERWANJI DUGGAN, I.M.S., Professor of Ophthalmic Medicine and Surgery, Grant Medical College, Bombay, and Superintendent of the Sir Cowasji Jehangir Ophthalmic Hospital, Bombay.
PIEDADE FELICIAN MATHIAS, Madras Medical Service, Superintendent, Government Royapuram Hospital, and Lecturer in Surgery, Royapuram Medical School, Madras.
IRVING DANIEL RAMSAY, M.D., Civil Surgeon, Ministry of Interior, Iraq.
GEORGE STUART, M.A., M.B., Ch.B., Assistant Director, Laboratories, Department of Health, Palestine.

M.B.E. (Military).

Medical Warrant Officer, *3rd Class Assistant Surgeon* ALFRED BACKMAN, Indian Medical Department, attached Iraq levies.

M.B.E. (Civil).

THOMAS FAWSITT, M.R.C.S., L.R.C.P. For public and charitable services in Oldham.
WILLIAM PATRICK SMYTHE MITCHELL, Indian Medical Department, Medical Officer, Bastar State, Central Provinces.
JAMES HERBERT THEODORE, Indian Medical Department, King Institute, Guindy, Madras.
SOCRATES NORONHA, Medical Officer in charge, Anti-Venereal Department, Bombay Municipality.
CHARLES ROBERT PHILIP, M.B., East African Medical Service, Medical Officer, Kenya.

Kaisar-i-Hind Medal (First Class).

GEORGE BARNES ARCHER, M.D., Medical Officer, Medical Mission, Dayabari, Ranaghat, Nadia, Bengal.

The honour of Knighthood has been conferred also upon JAMES R. JACKSON, M.R.C.V.S., Chief Veterinary Officer, Ministry of Agriculture and Fisheries, and upon P. CHALMERS MITCHELL, C.B.E., M.A., LL.D., D.Sc., F.R.S., Secretary of the Zoological Society.

THE GENERAL ELECTION.

MEDICAL MEMBERS OF THE NEW PARLIAMENT.

THE following nine medical men who were members of the last Parliament have been re-elected to the House of Commons at the recent General Election:

Dr. A. VERNON DAVIES (C.), Lancaster (Royton).
Dr. W. E. ELLIOT (C.), Glasgow (Kelvingrove).
Dr. F. E. FREMANTLE (C.), Hertfordshire (St. Albans).
Dr. H. C. HASLAM (C.), Lincolnshire (Horncastle).
Dr. E. GRAHAM LITTLE (Ind.), London University.
Dr. ALFRED SALTER (Lab.), Bermondsey (West).
Professor THOMAS SINCLAIR (C.), Queen's University, Belfast. Returned unopposed.
Dr. DRUMMOND SHIELS (Lab.), Edinburgh (East).
Dr. J. H. WILLIAMS (Lab.), Carmarthen (Llanelly).

The following eight members of the medical profession have also been elected; several of them have sat as members of the House of Commons in previous Parliaments.

The Right Hon. CHRISTOPHER ADDISON (Lab.), Swindon.
Dr. ETHEL BENTHAM (Lab.), Islington (East).
Dr. ROBERT FORGAN (Lab.), Renfrew (Western).
Mr. SOMERVILLE HASTINGS (Lab.), Reading.
Dr. JOSEPH HUNTER (L.), Dumfries.
Dr. H. B. MORGAN (Lab.), Camberwell (North-West).
Dr. J. H. *MORRIS-JONES (L.), Denbigh.*
Dr. G. E. SPERO (Lab.), Fulham (West).

Of the seventeen successful medical candidates, nine belong to the Labour party, five are Conservatives, two are Liberals, and one is an Independent. Dr. Ethel Bentham has the distinction of being the first medical woman to enter Parliament.

Sir George Berry (C.), who was one of the three representatives of the combined Scottish Universities in the late Parliament, is standing again, and another medical candidate for that constituency is Dr. J. Kerr (Lab.). The result has not yet been declared.

Polling Figures.

The following are the polling figures at all the contested elections in which medical candidates were successful. An asterisk denotes that a candidate sat in the last Parliament.

SWINDON (WILTS):	
Dr. C. Addison (Lab.)	16,885
*Sir R. Mitchell Banks (C.)	14,724
F. C. Thornborough (L.)	7,060
ISLINGTON (EAST):	
Dr. Ethel Bentham (Lab.)	15,199
*Major R. I. Tasker (C.)	13,541
E. C. Middleton (L.)	11,136
LANCASTER (ROYTON):	
*Dr. A. Vernon Davies (C.)	15,051
H. Derbyshire (L.)	13,347
A. E. Wood (Lab.)	10,763
GLASGOW (KELVINGROVE):	
*Dr. W. E. *Elliot (C.)*	17,037
J. Winning (Lab.)	15,173
W. Reid (L.)	2,623
RENFREW (WESTERN):	
Dr. R. Forgan (Lab.)	14,419
A. T Taylor (C.)	12,183
F. S. Anderson (L.)	2,682
R E. Muirhead (Scottish Nat.)	1,667
HERTFORDSHIRE (ST. ALBANS):	
*Dr F. E. Fremantle (C.)	20,436
Miss M. Whateley (Lab.)	11,699
G G. Honeyman (L.)	10,299
LINCOLNSHIRE (HORNCASTLE):	
*Dr. H. C. Haslam (C.)	12,837
F. C. Linfield (L.)	10,168
J. R Sanderson (Lab.)	3,683
READING:	
Mr. Somerville Hastings (Lab.)	23,281
*H. G Williams (C.)	22,419
D. Macfadyen (L.)	7,733
DUMFRIES:	
Dr. J. Hunter (L.)	16,174
*Brig.-General J. Charteris (C.)	12,984
W. H. Marwick (Lab.)	6,637
UNIVERSITY OF LONDON:	
*Dr. E. Graham Little (Ind.)	5,859
W. T. Layton (L.)	2,923
Sir John Gilbert (C.)	2,179
CAMBERWELL (NORTH-WEST):	
Dr H. B. Morgan (Lab.)	12,213
*E T. Campbell (C.)	9,808
H. Harcourt (L.)	5,559
DENBIGH:	
Dr. J H. Morris-Jones (L.)	21,305
A. Graham (C.)	13,116
BERMONDSEY (WEST):	
*Dr. A. Salter (Lab.)	13,231
L. J. Stein (L.)	4,855
Lieut.-Colonel H. C. Butcher (C.)	3,852
EDINBURGH (EAST):	
*Dr. Drummond Shiels (Lab.)	13,933
T. P McDonald (L.)	8,587
R. C. Thyne (C.)	6,639
FULHAM (WEST):	
Dr. G. E. Spero (Lab.)	16,190
*Sir Cyril Cobb (C.)	13,979
G. A. Gale (L.)	5,920
CARMARTHEN (LLANELLY)	
*Dr. J. H. Williams (Lab.)	28,595
R. T. Evans (L.)	15,065
J. P. L. Thomas (C.)	3,999

Unsuccessful Candidates.

The following members of the medical profession were defeated at the polls. Several of them had previously represented or contested either the same or other constituencies. An asterisk denotes that a candidate sat in the last Parliament.

Dr. C. W. Brook (Lab.), Wandsworth (Balham and Tooting).
Dr. F. G. Bushnell (Lab.), Birmingham (Moseley).
Dr. Stella Churchill (Lab.), Brentford and Chiswick.
Dr. J. D. *Cooke (C.), Camberwell (Peckham).*
Dr. C. R. Cooke-Taylor (L.), Camberwell (Dulwich).
Dr. R. Dunstan (Com.), Bethnal Green (South-West).
Dr. L. Haden Guest (C.), Salford (North).
Dr. A. B. Howitt (C.), Preston.
*Sir Henry Jackson (C.), Wandsworth (Central).
Dr. J. W. Leech (C.), Newcastle-upon-Tyne (West).
*Sir Richard *Luce (C.)*, Derby.
Dr. R. Lyons (Lab.), Middlesex (Hendon).
Dr. R. A. Lyster (Lab.), Hampshire (Winchester).
Dr. R. O. Moon (L.), Oxford.
Dr. J. Fraser Orr (L.), Linlithgow.
Dr. Joseph Robinson (Lab.), Manchester (Withington).
Dr. J. V. Shaw (L.), Derbyshire (Ilkeston).
Dr. W. H. Summerskill (L.), Wandsworth (Balham and Tooting).
*Sir Thomas Watts (C.), Manchester (Withington).

British Medical Journal.

SATURDAY, JUNE 8TH, 1929.

ENCEPHALITIS LETHARGICA AND JUVENILE DELINQUENCY.

THE age-long problem of troublesome youth has within the last ten years been complicated to some extent by the intrusion of encephalitis lethargica into the list of organic diseases which seriously disturb the mental processes of the patient and profoundly alter his character and conduct. Fortunately, in respect to the population at large, the individuals who are each year seriously attacked by this disease are few in number; and, although some 30 to 40 per cent. of such persons, in greater or less degree, become changed in character, they do not swell the sum of delinquency to any serious extent. Thus a recent report issued by the Home Office[1] shows that at the end of 1926 there were 6,871 boys and girls under reformatory training in Home Office schools, whereas the total number of juveniles sent to these schools on account of post-encephalitic delinquency during the period 1920–27 numbered only 108; in Borstal institutions and prisons also the post-encephalitic subjects do not form a large proportion of the inmates as a whole. But in the general lump of juvenile delinquency, wherever it may be found—in special schools, reformatories, mental hospitals, or penal places—the post-encephalitic constituent is an active and disquieting leaven. There are several reasons why, in spite of their relatively insignificant numbers, post-encephalitis delinquents—chiefly children and adolescents, with males preponderating—should attract special attention. In the first place, the causes and circumstances of their plight are different from those which obtain in the case of certain other classes of delinquent. Thus it is by no means usual to find any strong antecedent evidence of mental instability either in the delinquent or his parents; still less frequently can the home environment of the patient be said to have contributed materially to his condition; and among school children it is notorious that the mentally backward or temperamentally troublesome scholar does not succumb to the disease so often as does the well-behaved child of good or exceptional ability.

The failure to adapt themselves to their social environment which certain sufferers from encephalitis lethargica share with other types of delinquents seems to arise mainly from a condition of irritability combined with motor restlessness (especially marked at night) and emotional instability; there is a loss of volitional control, and, generally speaking, the changes appear to be regressive in character and associated with various forms of misbehaviour of a primitive and instinctive type. McCowan and Cook[2] are inclined to agree with Auden[3] that the behaviour changes in encephalitic subjects are partly brought about by "regression due to removal or suppression of the epicritic control over the protopathic instinctive tendencies." In [illegible] most observers consider that the [illegible] equal to the best summer butter tested.

Messrs. Lever Brothers have submitted to us the [illegible]'s Branch, a second series of tests carried out in another laboratory, to show that the vitamin concentrates used in manufacture [illegible] a satisfactory vitamin content, and also confirm Dr. Coward's finding that the finished margarine has a vitamin content equal to that of good butter.

[illegible] content, and that they were superior [illegible] impairment of their intellect, and, as one authority puts it, "the encephalitic is almost invariably intellectually superior to his conduct."

The changes in behaviour—which some authors, like Wimmer,[4] consider show uniformity in different patients, but which Shrubsall[5] thinks are coloured by the individual patient's previous experience—are manifold and often strange, while they vary in importance from an unnatural irritability to homicidal tendencies. Irritability may show itself in general restlessness, interference with others, teasing, abusive language, destructiveness, and in many other ways; motor restlessness seeks an outlet in wandering—especially at night—truancy, queer antics, fighting, and occasionally in acts of daring involving some degree of personal courage. Emotional disturbances are reflected in fits of laughter or crying, and in such directions as general noisiness, rowdyism, etc. The more serious effects of a loss in volitional control which bring the subject within the arm of the law are such malpractices as lying, thieving, arson, sexual offences, assault, and even homicide. But in association with such examples of misbehaviour and crime, many of which apply to other forms of delinquency, there are certain temperamental and physical attributes of the encephalitic delinquent which have attracted attention. Thus Shrubsall[5] has pointed out the encephalitic child's desire to attract notice, and the same morbid craving for attention is reported of encephalitis lethargica patients in the West Park Mental Hospital; a child in another institution would, as a matter of routine when visitors were present, let herself fall from a ladder during a physical exercise class in order to attract attention. Another characteristic trait in encephalitic delinquents is their readiness to express, and to show, sincere contrition for their misdemeanours, which they recognize as such, and to the committal of which they say they are overwhelmingly compelled; moreover, there is sometimes the wish, if not the will, to improve, as in the case of a girl of 13 at Winchmore Hill, who would say: "Can I stay upstairs by myself until school time? I feel I am going to fight." At the same time, other patients are less honest with themselves, and furnish all sorts of ingenious, if not ingenuous, excuses.

Professor René Cruchet, in his graphic narrative which appears at page 1028 of our present issue, illustrates in the case of one of his patients several of the points touched upon above. He also emphasizes the fact that, with the progressive deterioration in conduct as the boy grew up, there was no arrest in physical development and strength. In this connexion we may recall that T. R. Hill[6] has found that when the physical symptoms of Parkinsonism supervene the tendencies to delinquency begin to decline, and then to disappear when this condition becomes pronounced.

The encephalitic delinquents as a class are remarkable for the special difficulties which their treatment and after-care involve. They apparently do not react satisfactorily to the reformative treatment which in Home Office schools and Borstal institutions has proved successful in the case of other types of youthful offenders. As mental patients McCowan and Cook[2] consider that "the encephalitics are the most troublesome and pugnacious children in the ward." The prospects of a thorough reformation in character seem, indeed, to be remote in many of the graver cases of post-encephalitis. But this should not yet discourage

the laudable efforts at salvage and the patient research work which is being carried on at such institutions as the Northern Hospital, Winchmore Hill, the West Park Hospital, Epsom, the Southmead Hospital, Bristol, and others; nor can the special value of such comprehensive and informative case-histories as that given by Professor Cruchet be overestimated. A ray of hope has recently been emitted from the Winchmore Hill Unit, where Hill[7] has been able apparently to improve the habits and general conduct of certain patients by the use of bulbocapnine, a drug related to apomorphine.

THE TREATMENT OF TUBERCULOUS ADENITIS.

"PLUS ça change plus c'est la même chose" is an adage which, if not true of all medical problems, can certainly be applied to the methods of treating tuberculous glands in the neck. Some thirty years ago a radical enucleation of the glands was the accepted routine practice; there followed a vogue of conservative methods, of which the most important was based on removing the supposed primary focus of infection and relying on the natural or stimulated resistance to overcome infection in the glands. Other procedures were often empirical, but in general fell into line with methods used in the treatment of other types of tuberculous infection. Conservative measures have been given a fair trial, and still have ardent advocates; if, however, we accept the evidence which Mr. Gordon Bruce gives in our present issue (p. 1030), it would appear that the full circle has been turned, and that surgical treatment is once again to be regarded as the method of choice for the majority of established infections. Mr. Bruce, basing his conclusions on a study of 330 cases of cervical adenitis treated during four consecutive years at Aberdeen, strongly advocates the radical excision of glands diagnosed as tuberculous in which there is clinical evidence of caseation. From his investigations he is satisfied that this condition is present in all glands which have been subject to alternate attacks of swelling and periods of quiescence. He finds that removal of diseased tonsils has no marked effect on the glandular condition, and is frankly sceptical of the value of heliotherapy in relation to the local condition of all but early cases. In support of the latter view he quotes Dr. Margaret Tod, who, in surveying a group of cases treated by this means in Edinburgh, stated that in no case had it effected a cure.

If these gland infections are recognized as being local rather than systemic in nature, the radical removal of the diseased tissue, so far as is practicable, presents itself as a sound procedure. Mr. Gordon Bruce is clearly of the opinion that few cases of tuberculous adenitis are blood infections, adducing as evidence the fact that in 90.6 per cent. of his series the infection was apparently limited to the gland area operated on. In no case belonging to this group was there found evidence of tuberculous infection elsewhere before or after operation. The argument for radical excision is further supported by the view that once caseation is well established complete resolution without operation does not occur. In this event removal of a primary focus of infection, such as the tonsil, cannot be expected to do more than prevent further infection. There is no doubt that in many cases apparently cured by conservative methods the infection in the glands has been not tuberculous, but streptococcal. Streptococcal infections may precede or accompany tuberculous infection in some instances, or they may be the sole lesion in chronically enlarged glands. In general they are present in the early stage, but may remain dormant for a considerable time, causing a flare-up in the wound after a radical operation. It is interesting to note that in 187 operations performed by Mr. Bruce 9 patients developed secondary streptococcal infection of a severity which was thought worth recording.

It has been a matter of discussion how far conclusions based on the results obtained in the treatment of tuberculosis in Scotland are valid in England. There is evidence that the clinical course of tuberculosis in Scotland differs from that in the south; moreover, in Scotland, in both bone and gland disease, there is a higher incidence of infection with the bovine organism. In his report to the Science Committee of the British Medical Association, published in the *British Medical Journal* of January 17th, 1914 (p. 125), Philp Mitchell made the following statement: "Cow's milk containing bovine tubercle bacilli is clearly the cause of 90 per cent. of the cases of tuberculous cervical glands in infants and children residing in Edinburgh and district, and is responsible for by far the larger proportion of tuberculous cervical glands in children during the milk-drinking period of life (0 to 5 years)." There does not appear to be any conclusive evidence as to the exact type of organism responsible for adenitis in the southern area of Britain.

Mr. Gordon Bruce's most important conclusions are that glands in the neck remaining persistently enlarged after three months are nearly always tuberculous in nature, and that if there is clinical evidence of their having undergone caseation the most satisfactory results are obtained by their enucleation. The complications of extracapsular abscess and sinus formation handicap the surgeon in his dissection; they do not contraindicate operation, but lead to a lower standard of final results, both as to scar condition and permanency. These views are worth careful study; certainly most surgeons at the present time, though they would probably give conservative methods a trial for longer than three months, tend to conform to them. The surgery of the radical operation is not simple; injuries to important nerves and major blood vessels have not always been avoided, and in this connexion Mr. Bruce's paper contains a considerable amount of interesting detail.

NEUROLOGY AND LIFE.

THE Earl Grey Memorial Lecture[1] recently delivered by Sir Farquhar Buzzard offers a pleasing educational opportunity to any who may be inclined to limit the range and influence of medicine to technical and professional ends. Equally, the lecture may be commended to those who are disposed to think that physiological investigations and the doctrines that result from these are remote from medical practice and the life of the world. A third group of readers may be invited—namely, all those who appreciate the presentation of a scientific record in a systematic fashion, and with logical sequence and literary charm. Alike to the medical and the lay reader, Sir Farquhar's lecture will be both a welcome and an instructive experience. The lectureship was established as a tribute to the memory of a statesman and administrator who made a large contribution to the wise policy on which are laid the foundations of the British Empire, and the text of the lecture is expected to be a topic of educational or social importance. Sir Farquhar Buzzard's thesis is that the developing

[1] *An Outline of Neurology and its Outlook*. By Sir E. Farquhar Buzzard, K.C.V.O., M.D., F.R.C.P. London: Milford, Oxford University Press. 1929. (Med. 8vo, pp. 24. 1s. net.)

knowledge of neurology and the outlook thus created form a theme that comes within this definition. In a singularly lucid and masterly fashion he describes how step by step and through the centuries the truth about the structure and functions of the nervous system has been acquired, and how anatomy, physiology, pathology, clinical observation, and, more recently, psychology have made their several contributions to this end. This historical sketch forms the main portion of the lecture, and is presented with a degree of competence and clearness that deserves grateful recognition. Then comes the outlook and the argument. From the structural facts and domestic activities of the nervous system of the human body we are invited to pass to the proposition that "education and sociology alike are based, or should be based, on what knowledge we possess of the individual and communal reactions of the nervous system to external influences." It is on the truths of physiology, and not on benevolent emotions, that the educationist and the sociologist must build would they have for their policies a secure foundation. At present there are hindrances. First, the full significance of certain physiological facts cannot yet be accurately defined. In the second place, there is no large public equipped with the elementary knowledge and sense of responsibility necessary to the profitable reception of "the rich harvest of scientific facts and laws which is now being reaped." Physiology in some of its departments has yet to gain in precision, and, still more, public opinion has to be informed and educated until it is ready to face facts and to "abandon a mediæval faith in miraculous cures." To the clinician and the pathologist Sir Farquhar Buzzard gives credit for definitely showing that the brain is the organ of mind, and that all forms of mental disorder are related to changes in the highest part of the nervous system. Pavlov's studies of the conditioned reflex he regards as offering an opportunity for the investigation of the higher levels of the cerebral activities, and here he anticipates results which "must sooner or later disturb the peaceful dreams of educationists." As a further illustration of the relation between education and cerebral structure and function he quotes the alterations in moral and mental attributes that may follow an attack of encephalitis lethargica, where what has been attained by years of mental and moral training may entirely disappear as a result of structural cerebral changes. Such an experience, he recognizes, "makes it difficult to preserve quite intact older conceptions of a soul or of a conscience, and almost impossible to draw a clear line of demarcation between body and spirit." Again, another approach to the workings of the mind is opened by studies in psychology and psycho-pathology, and Freud's work and teaching have, in Sir Farquhar's judgement, thrown much light "on the obscure origin of many forms of minor mental disorder." Between physiological inhibition on the one hand, and the psychological repression of Freud on the other, there may be suggested a relationship which "dimly foreshadows the ultimate conciliation of two separate attempts to solve the same great problem—the workings, ordered and disordered, of the human mind." In all this there is abundant proof that neurology includes within its scope truths to which the educationist and the sociologist must needs give ear, and the audience may even be enlarged by the addition of the philosopher and the theologian.

HAIR DYES.

IT is true that the harassed medical student has not yet to be "signed up" in hair dyeing before he may satisfy his examiners that he is fit to practise, but the subject is by no means devoid of medical interest. Never before in the history of the world would people seem to have been so reluctant to accept philosophically the approach of old age; never so much as to-day have the resources of the chemist been made to serve the desire to maintain a youthful appearance. While, however, the chemist may take some pride in the efficiency of the innumerable dyes which have been devised to mask the presence of white hairs—so shattering, apparently, to the illusion of youth—the physician's interest is engaged by the fact that many of the chemicals employed are far from harmless and that his services are sometimes invoked to treat cases of poisoning brought about by their application. Notwithstanding the efforts of the practitioners of cosmetic arts to veil their proceedings in mystery, a great deal of information bearing on the subject may be gleaned from the trade publications serving the members of the hairdressing profession and from scattered papers in various chemical journals. We welcome, however, the publication of the book which bears the intriguing title *Blonde or Brunette?*[1] for within its small compass the authors have collected, and presented, simply yet scientifically, all that the medical man needs to know about this subject. It is interesting to read that henna, which has enjoyed a high reputation since Biblical times, and is still largely used for cosmetic purposes, might be considered the ideal hair dye, but for the fact that it requires more skill in its application than some other substances. Successfully applied, it gives a wide range of good colours, and has the great advantage of being perfectly harmless. To-day the ideal hair dye must not only produce with safety a permanent colour, natural in appearance, but it must not render the hair less responsive to the treatment known as permanent waving. In this respect the metallic dyes fail, though all of them which depend for their action on the reduction of silver or some other metal by a solution of pyrogallol are in other respects quite satisfactory. It is on account of this unfortunate defect in the metallic dyes that hairdressers are greatly tempted to employ the convenient dyeing agent paraphenylenediamine (known to the trade as "para"), which is endowed with all the attributes of the perfect hair dye, except that it is extremely toxic to susceptible persons. In these it produces a virulent dermatitis, which may extend far beyond the area of its application, and has even been known to affect the whole cutaneous surface. If, moreover, the victim of an attack is so foolhardy as to risk further contact with the exciting substance she will suffer even more severely than she did the first time. The fact that only 1 per cent. of healthy persons are susceptible encourages many hairdressers to risk using this chemical without testing their client's sensitiveness. The test is carried out quite simply, by applying a small quantity of "para" to the skin behind the ear and waiting twenty-four hours for the possible development of erythema. If the skin remains normal in that time the dye may be applied with safety. The fact that paraphenylenediamine gives the required tint almost instantaneously, while pyro-reduction dyes require forty-eight hours to achieve their effect, is an additional source of temptation to the hairdresser, especially when a client demands cosmetic treatment before attending a social function the same evening. The toxic qualities of "para" are so well known to the trade that hairdressers have occasionally tried to escape the wrath of poisoned clients by denying its use, alleging that they had applied a dye of the pyro group; this defence, however, can never deceive those who know the instantaneous tint produced by the former and the delayed action of the latter. Pyro-reduction dyes are irritant only if the pyrogallol solution is of excessive strength. Medical men who desire to know more of the technique of hair dyeing, the chemistry of the dyes used, and their effects on the health and appearance of the hair, would do well to consult this concise treatise.

[1] *Blonde or Brunette?* By H. Stanley Redgrove, B.Sc., A.I.C., and Gilbert A. Foan, President of the Hairdressers' Trade Parliamentary Committee. London: W. Heinemann (Medical Books) Ltd. 1929. (Demy 8vo, pp. xii + 182; 28 figures. 7s. 6d. net.)

GOLDSMITH AND MEDICINE.

AMONG the numerous celebrations of this and last year one of unusual interest from a medical point of view, on account of some debatable details, is the bicentenary of Oliver Goldsmith (1728-1774). In our issue of March 9th (p. 469) we reported an address full of detailed information delivered by Dr. T. P. C. Kirkpatrick, Registrar of the Royal College of Physicians of Ireland, and the outstanding authority on the history of Irish medicine, on "Goldsmith in Trinity College and his connexion with medicine."[1] Dr. Kirkpatrick asserted that (contrary to a widely held belief) Goldsmith, rejected for the Church and for a short time considering the study of law, began his medical studies not at Trinity College, where he graduated in arts in 1750, but two years later, first in Edinburgh, then at Leyden, Paris, and elsewhere. There appears to be no sound foundation for Frankfort Moore's suggestion that Goldsmith intended to adopt "the profession of a medical student," a practice which was not uncommon in the following century, and, indeed, then often seemed adequately to fill a man's lifetime. The question of where Goldsmith obtained his M.B. degree has been much discussed and investigated; at the Section of the History of Medicine of the Royal Society of Medicine in 1914 it was suggested that he deceived the University of Oxford when, on February 14th, 1769, he got an *ad eundem* degree of M.B. by describing himself as an M.B. of Dublin. Dr. Kirkpatrick, after careful consideration of all the circumstances—among them the fact that medical degrees were sometimes granted by the University of Dublin without examination, as occurred in the case of Richard Brocklesby, also a friend of Dr. Samuel Johnson—suggests, though without dogmatism, the possibility that Goldsmith may have had the M.B. degree of Dublin University conferred upon him *in absentia*. Unfortunately, after his visit to Oxford, his interest in physic became mainly that of the patient rather than of the practitioner. There must always be some doubt about the nature of his final illness and his own responsibility for its termination. Against the advice of Drs. Hawes and George Fordyce, he obstinately persisted in dosing himself with Dr. Robert James's fever powder, though Dr. Kirkpatrick believes that neither the powder nor any other treatment employed can be justly blamed, and cautiously suggests that Goldsmith's chief complaint was some form of chronic nephritis, which terminated in uraemia.

WELSH NATIONAL SCHOOL OF MEDICINE.

AFTER a year of discussions and negotiations between the various interested parties, there seems every prospect that the Welsh National School of Medicine will be able to make a fresh start in the autumn. It will be remembered that last summer, owing to the refusal of the staff of the Cardiff Royal Infirmary to co-operate in the teaching of the final-year subjects, the senior students of the school had to leave Cardiff and continue their studies elsewhere, and the school was finally shut down when the Royal Infirmary definitely closed its doors to all students. It was unthinkable that an educational institution of such promise should be allowed to founder in this way, and we are very glad to learn that an agreement has been reached between the University of Wales, Cardiff College, and the Royal Infirmary which will enable the school to reopen once more, and, it is hoped, guard against the repetition of last year's catastrophe. The agreement, which is for seven years in the first instance, accepts the principle of the unit system, establishes a board of clinical studies by which considerable executive responsibility is given to the hospital staff, and, most important of all, provides that all the beds in the Infirmary shall be available for teaching. This last is really the vital point, for the clinical facilities at the Infirmary are by no means excessive, and unless they can be utilized to the full it would not be possible to provide for a comprehensive clinical training. Since the Cardiff students usually combine the Welsh degree with the degrees of London University or the diplomas of the English Conjoint Board, these authorities are naturally concerned with the facilities for clinical teaching available at Cardiff; they demand that all the resources of the Infirmary shall be utilized to the full, and this implies the active co-operation of all the members of the staff, for, speaking generally, it is not possible for one man to teach on another man's patients. At the meeting of the Infirmary Board of Management when the agreement was ratified there appeared somewhat disquieting indications that the medical members were still unwilling to assent to the principle that a staff appointment should carry with it the obligation to teach. The lay members, however, were emphatic on this point, and it was laid down quite clearly that the clause in the agreement which places all the Infirmary beds at the disposal of the school must also be taken to mean that every member of the staff shall co-operate in the work of the school. The agreement appears to offer a sound working basis, and it is sincerely to be hoped that all the contracting parties will faithfully observe it in the spirit as well as in the letter. The Welsh School of Medicine could hardly survive another breakdown, and if this agreement fails to solve the problem at issue the future outlook is black indeed. Modern medical education is such a costly matter that a reduction in the number of existing schools would seem a more justifiable policy than the creation of additional ones. Only by carefully fostering all its resources can the Welsh School of Medicine hope to succeed; the continuation of internal dissension must inevitably lead to a final collapse.

TRAFFIC IN DRUGS OF ADDICTION.

AFTER the day's work many of us enjoy an hour or two's relaxation in a world terrorized by international gangs of crooks and dominated by sinister geniuses with an anti-social complex. It is not a little startling when the amenities offered by sensational fiction are paralleled in a sober essay describing dispassionately what is actually happening around us. Yet the writer of fiction, jealous of his reputation for plausibility, would scarcely venture to strain our credulity with a picture as amazing as that presented by Dr. F. Redlich, who, in his book on drug intoxication and addiction,[1] tells us how international organizations, with agents all over the world, skilfully make use of every loophole in international laws and agreements to carry out their odious but profitable trade. He describes, for example, an organization controlled by two Russian merchants and a Russian doctor in Berlin, and a merchant in Reval, which worked east to Japan and west to Valparaiso. They bought drugs openly in Germany, and apparently dispatched them from Berlin to Rumania with all due legal formality. Once the forms were filled in, what they did was to remove the drugs from the packages through false bottoms, substitute inert chemicals, and dispatch these to the confederate in Rumania, who would then duly acknowledge their receipt. The drugs thus released from bond were disposed of in various ways; some were peddled in Berlin and Paris, some were sent to Russia and Persia, both of them countries outside the Opium Convention. The remainder were dispatched to the free port of Copenhagen, where they were coloured with charcoal, mixed with spirit, packed up attractively as cosmetics, shoe polish, etc., and sent to the Far East by way of Russia. The scale of the profits is indicated by

[1] *Irish Journ. Med. Sci.*, 1929, Sixth Series, No. 40, pp. 142-162.

[1] *Rauschgifte und Suchten.* Von Dr. phil. Fritz Redlich. Bonn: Kurt Schroeder. 1929. (Med. 8vo, pp. 88. M.4.50.)

the fact that cocaine bought in London for £20 was sold in the Far East for over £100; some of the drugs passed on from the Far East to America. The shipment of drugs from Chinese ports to America is controlled by organizations commanding large capital; one such organization in Hong-Kong is said to have a monthly turnover of 200,000 dollars. In 1927 a single shipment of drugs worth £5,000 was seized on a Canadian vessel. The profits from this amount may be estimated from the fact that the price of illicit drugs in Canada is nearly ten times the legal price, and the successful smuggling of a pound of cocaine would represent a profit of £250. Cuba and the islands of St. Pierre and Miquelon, on the east coast of America, are centres of illicit drug trade, but most of the smuggling is done across the Canadian border by bootleggers, who, for so profitable an industry, have practically unlimited funds at their disposal. Into China, the greatest market in the world for drugs of addiction, alkaloids and opium are smuggled through every conceivable route. We are not surprised to learn that Macao and Vladivostock are centres of this trade, but it is curious to read of opium smuggled on pony-back from Persia across Afghanistan to Chinese Turkestan, where each pony load fetches £160. The new motor track across the Syrian desert is already being used for the smuggling of cocaine into Baghdad. According to Dr. Redlich, morphinism and cocainism are spreading steadily in Asia, morphine addiction in particular having penetrated far into the interior of China, and being a greater danger to that country than the opium habit.

MORE FRUIT.

ACCORDING to a Chadwick lecturer, Mr. H. V. Taylor, commissioner of horticulture in the Ministry of Agriculture and Fisheries, every person in this country eats, on the average, 100 apples a year, 72 oranges, and 30 bananas. Indeed, from Mr. Taylor's lecture, which was delivered in the delightful old Chelsea Physic Garden on May 31st, one might almost suspect that we are becoming a race of fruitarians. Twenty years ago the annual production of fruit in this country was something like 400,000 tons; to-day it exceeds that figure by at least 100,000 tons, and in the meantime the supplies of imported fruit have increased enormously. Certain fruits and vegetables, now ranked as ordinary articles of diet, have appeared for the first time on our tables practically within the last generation. At the beginning of this century the cultivation of tomatoes, cucumbers, and other garden plants under glass was so small as not to be recorded; to-day the annual value of this industry exceeds five million pounds sterling. In the childhood of many of us the tomato was used only for pickling and the making of soups and sauces. Nowadays, thanks to cheap glass and facilities for keeping the temperature of glasshouses at a constant level, a million hundredweights of tomatoes a year from English gardens, another million from the Canary Islands, and not far short of a third million from the Channel Islands go to the making of salads, are consumed raw, or served in various appetizing ways. Five or six times as many bananas, again, are eaten now as was the case thirty years ago. The banana excited little interest before 1900, though the first box of this fruit came to this country about the middle eighties. Later a shipping company was formed for bringing bananas from Jamaica to Bristol, and now we spend three million pounds sterling on this product. As for apples, thanks now to methods of storing in ships which preserve their vitality during transport, we get apples all the year round. Not so long ago there was a part of the year (from April until the end of July) when apples were not forthcoming. Our own orchards supply three million hundredweights of apples annually, and seven or eight million hundredweights reach this country from the Dominions and elsewhere. Orange production is increasing enormously; wherever this popular fruit grows—as, for example, in Spain, Egypt, Palestine, and South Africa—increased plantations are being laid out, and within a year or two the imports of the orange bid fair to multiply exceedingly. Mr. Taylor exhibited a pipless orange, also a coreless apple, but said that this production, for which there was some demand, entailed a certain loss of flavour. The lecturer drew attention to the value of all these fruits, not so much as represented by calories, but in respect to vitamin content, "roughage," and mineral salts. He thought there could be no doubt that the increased consumption of fruit must be exercising a very beneficial effect upon the health of the people.

THE HONOURS LIST.

THE honours conferred on June 3rd, on the occasion of His Majesty's birthday, include a considerable number of awards to members of the medical profession; the full list of these will be found at page 1044. Our readers will share the general feeling of pleasure at the recognition which has been given to the services of those medical men who were concerned in the treatment of the King during his long illness—namely, Lord Dawson of Penn, Sir Humphry Rolleston, Sir Farquhar Buzzard, Sir Hugh Rigby, Sir Stanley Hewett, Dr. Francis Shipway, Dr. Robert Stanton Woods, Dr. H. K. Graham Hodgson, Dr. F. D. Howitt, Dr. L. E. H. Whitby, and Professor E. C. Dodds. Our colleagues in Australia will especially welcome the honours accorded to the Hon. Mr. E. C. G. Page, Commonwealth Treasurer, to Dr. Richard Stawell of Melbourne, and to Professor W. Colin Mackenzie, director of the National Museum of Australian Zoology, henceforth to be known as the Australian Institute of Anatomy. The principal Service distinction is the K.B.E. conferred upon Major-General Thomas H. Symons, formerly Surgeon-General, Madras, and now Director-General of the I.M.S. Although Dr. Robert Bridges, the Poet Laureate, long ago gave up the practice of medicine, his admission to the Order of Merit reflects honour upon the calling which first claimed the fruits of his pen.

THE annual general meeting of the Research Defence Society will be held at the House of the Medical Society of London, 11, Chandos Street, W.1, on Wednesday next, June 12th, at 3 p.m., with Lord Lamington in the chair. Professor A. V. Hill, F.R.S., will deliver the third Stephen Paget Memorial Lecture on "Enemies of knowledge." Tea and coffee will be served after the meeting.

THE KING.

ON May 31st it was announced from Windsor Castle that the King was confined to bed with a feverish attack. A bulletin issued on the following day stated that an abscess had formed on the right side of the chest, and was now draining; that His Majesty's general condition remained good; and that, though he would need to remain in bed, he would be able to transact public business. A later bulletin stated that the abscess was "so far following the normal course, which in the nature of things must be tedious." In accordance with the opinion of His Majesty's medical advisers, the Thanksgiving Service fixed for June 16th has been postponed.

The news of this interruption to His Majesty's recovery has been received with universal regret; but it does not give rise to anxiety, since the trouble has a local origin.

NINETY-SEVENTH ANNUAL MEETING of the British Medical Association, MANCHESTER, 1929.

THE ninety-seventh Annual Meeting of the British Medical Association will be held in Manchester this summer under the presidency of Mr. Arthur H. Burgess, F.R.C.S., Professor of Clinical Surgery in the University of Manchester, who will deliver his address to the Association on the evening of Tuesday, July 23rd. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 19th, at 9.30 a.m. The provisional programme for the nineteen Scientific Sections is published in the *Supplement* this week, and further details of the arrangements for the Annual Meeting will appear from time to time in later issues. We publish below the fourth of a series of descriptive and historical notes on Manchester and neighbourhood written for the occasion by Dr. E. M. Brockbank. The first article appeared on December 1st, 1928 (p. 1003), the second on January 26th, 1929 (p. 167), and the third on April 27th (p. 781).

THREE MANCHESTER LITERARY CELEBRITIES.

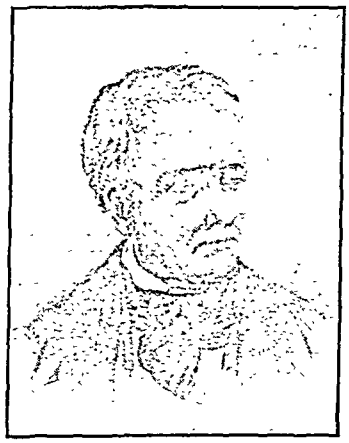
THREE widely read authors who were born or lived in Manchester—Thomas De Quincey, William Harrison Ainsworth, and Mrs. Gaskell—are specially interesting to us because their writings more or less intertwine with our medical history, fact or fiction.

THOMAS DE QUINCEY.

De Quincey was chiefly an imaginative essayist; he was born in Manchester in 1785, educated partly at the Grammar School, and spent most of his life, he said, in trying to get away from the town. But whatever his objection to Manchester may have been, it was not the cause of his opium eating. As a boy he knew Charles White and Thomas Percival, and had a certain amount to say about both which gives some insight into their personalities. White he met when he was attending professionally a lady to whom De Quincey was giving lessons in French. He writes of his visit to White's museum, about which he only remembered what he called the humanities in it—namely, a mummy and a skeleton. He tells us how one of White's lady patients left him £25,000 on condition that on her death he would have her body embalmed and put in a case with a veil over the face, and that once a year he and two witnesses of credit should withdraw the veil. The lady was placed in a common clock-case with the usual glass face, but a veil of white velvet obscured from all profane eyes the silent features behind. The clock he saw as a child and gazed on it with "inexpressible awe." Rumour named a certain lady as having left the bequest in her will, but a lawyer of Manchester about the end of the last century, after I had myself helped to perpetuate the rumour, found the lady's will at Chester, and there was nothing of the kind in it. However, the story suited De Quincey's taste for imaginative romance. The other humanity was the skeleton of a highwayman who had been executed for murder, and he interests us as he was a Knutsford man, Higgins by name, who formed the central character in Mrs. Gaskell's tale "The Squire's Story."

Another note about White was in connexion with De Quincey's sister who died at the age of 9. She was of "premature intellectual grandeur," and White, who was specially interested in craniology, pronounced her head to be the finest in development of any that he had ever seen. It must have been an unusually large head, because De Quincey, not wishing to mislead his readers, says she died of hydrocephalus. De Quincey also gives us an interesting sketch of Dr. Percival, who attended him, his brothers and sisters in their childish ailments. They all liked him very much, but their mother disliked him equally, and feared his "tolerant" views on religious matters, which he used to discuss with her, Percival being a Unitarian.

De Quincey was a prolific writer, almost entirely for journals. His *Confessions of an English Opium Eater* are well known to medical readers.



THOMAS DE QUINCEY.

HARRISON AINSWORTH.

William Harrison Ainsworth was born in Manchester in 1805, but lived most of his life in London. He was cousin to Dr. James Ainsworth, one of the early teachers of medical students here. In somewhat flamboyant style he wrote many very readable historical novels, the most widely known of which are *Guy Fawkes*, *Windsor Castle*, *Old St. Paul's*, *The Tower of London*, and *The Lancashire Witches*. Other tales about Lancashire incidents have a more local interest. Part of the action in *Guy Fawkes* takes place in Manchester, but that of the less known and less powerful *Manchester Rebels*, which has for its theme the '45, is almost entirely concerned with real and fictitious Manchester people, and the part they played in the Young Pretender's visits to the town on the march of the Highlanders cocking their bonnets to Derby, and during the army's retreat thence with fallen hopes.

Many young Manchester men joined the army, and the Manchester Regiment was formed of them. One of the Loyalist citizens was Dr. Peter Mainwaring, physician to the Infirmary, whose house, built in 1736, still exists in a fine state of preservation in King Street, and is a beautiful example of brickwork. It is now occupied by a branch of the District Bank. Amongst those who joined the Manchester Regiment was a son of Dr. Deacon, who had a small practice in the town, and Thomas Sydall. These, amongst other Manchester men, were hanged and quartered in 1748, and their heads sent to Manchester, where they were spiked on the first Exchange. There they remained as a warning to disloyal persons until 1749, when they

suddenly and mysteriously disappeared one night, having been removed (as we shall see in a moment) by a young Jacobite medical student, Edward Hall, afterwards surgeon to the Infirmary. They were buried in the Halls' garden at the top of King Street, and there they rested until the death of his sister, a staunch Jacobite, in 1828. When she knew for certain that she was dying she revealed the mystery by telling Dr. (afterwards *Sir*) *James Lomax Bardsley*, her medical attendant, the facts about the removal of the skulls and their burial, asking him to have them interred in consecrated ground, which he did, in St. Ann's churchyard.

A charming account of these times has been left us in her diary by a spirited Manchester girl, at heart an admirer of the Bonnie Prince, Elizabeth or Beppy Byrom, who is introduced into Ainsworth's novel amongst the incidents of the Scots' visit to the town. Her father, *Dr. John Byrom*, was a well-known literary man and poet, but not a medical man. He wrote the hymn "Christians Awake" and the celebrated blessing,

> "God bless the King, I mean the faith's defender;
> God bless—no harm in blessing—the Pretender;
> But who Pretender is, or who is King—
> God bless us all—that's quite another thing."

He was Jacobite, too, at heart, but evidently a careful one.

In those days many Manchester men, like many others, when drinking the toast of their King passed their glasses over a water jug or bottle—"the King over the water."

A romantic tale of Ainsworth's of local interest is *The Lancashire Witches*, which is concerned with the abortive Pilgrimage of Grace, its tragic consequences to John Paslew, last abbot of Whalley, and the part the witches of Pendle Forest were reputed at the time to have played in both. It is of general interest to know that claim is made in the tale for Hoghton Tower, near Blackburn, as the place where the "surloin" of beef—then known by such an anatomical description—was formally knighted by James I as being entitled to such an honour; and who will say that there is no "damned merit" in a sirloin, whatever one of the Victorian premiers might have thought of the K.G.? Almost as many places and kings lay claim to such an honourable act as there were birthplaces of Homer—Smyrna, Chios, Colophon, Salamis, Rhodos, Argos, Athenae, as they are stated in his metre. Unfortunately, in this matter Lancashire cannot lay claim with the same confident assurance that it so often does to having led in a national event, for it is stated with equal certainty that Henry VIII, after an episode with the Abbot of Reading, forestalled his sister's great-grandson and us in the matter.

HARRISON AINSWORTH.

There is no special interest to medical practitioners unless, may be, to psychologists, in the story of the Lancashire Witches; but perhaps it is only fair to repeat the warning to those visitors who have not been to our county before, of the last few lines of this romantic tale:

"Jennet was the last of the Lancashire Witches. Ever since then witchcraft has taken a new form with the ladies of the county—though their fascination and spells are as potent as ever. Few can escape them—few desire to do so. But to all who are afraid of a bright eye and a blooming cheek, and who desire to adhere to a bachelor's condition, to such I should say, Beware of the Witches of Lancashire."

ELIZABETH CLEGHORN GASKELL.

MRS. GASKELL.

The writer most identified with Manchester, and of most interest to us in recreation hours, was Elizabeth Cleghorn *Gaskell*, who was born on September 29th, 1810, in Chelsea. She was the daughter of William Stevenson, formerly a Unitarian minister, but later in life Keeper of the Records to the Treasury of London. He was a man of rare attainments, which his daughter inherited. Her mother was a daughter of Mr. Holland of Sandlebridge, near Knutsford, a member of a well-known county family. Many years of her early life were spent at Knutsford, which she has immortalized in her books, and in 1832 she was married there to the Rev. William Gaskell, minister of the Unitarian Chapel, Cross Street, Manchester. In 1844 she lost her only son, who died of scarlet fever. To divert her mind from grief at her great loss her husband suggested that she should try and write a story about her experience among the poorest classes in Ancoats, and this she did. *Mary Barton* was the result; and it was returned unread by the publishers to whom she first sent it. More successful on her second venture, the book was published anonymously and met with a great reception. She "awoke one morning to find herself famous," so to speak.

She wrote, in all, thirty-six long and short stories, all of which dealt with simple characters. Many of her tales are about the labour problems of her day, written with a heartfelt sympathy for the workers, but, as the masters thought, without fully appreciating their own difficulties in the hungry forties and during the great increase in the use of machinery in their factories. She lived all her married life in Manchester, but died suddenly and unexpectedly from heart failure when chatting with her daughters in 1865 at Acton in Hampshire, where she had just bought a house, after only a short period of ill health.

Mrs. Gaskell was related to doctors, and thereby hang three tales. Her uncle Peter Holland, who was the father of Sir Henry Holland, court physician and grandfather of the present Lord Knutsford, was a country surgeon. He resided at Sandlebridge and practised there and in Knutsford and the neighbourhood. It was at his house that Lord Clive spent some boyhood holidays, and where the story of his early daring originated, for he liked to terrify the Hollands by jumping from the ball on the top of one of the gateposts to its fellow on the other side. Mrs. Gaskell used to accompany Peter Holland on his rounds. Whilst she did not take him as her model for her finest medical character Dr. Gibson (one of her daughters saying that no two people could be more unlike each other), she could hardly have helped forming some of her knowledge of country doctors from Uncle Holland's practice and patients. A doctor is the chief character in her novels *Mr. Harrison's Confessions* and *Wives and Daughters*, and another is a prominent figure in *Cranford*, and all the scenes are sketched from Knutsford, Sandlebridge, and neighbourhood.

The first essay at portraying a country practitioner is in *Mr. Harrison's Confessions*, a short story of seventy pages or so. Here we have the experiences of a young doctor who began practice as assistant to Mr. Morgan, an elderly bachelor surgeon in a country town, with many spinsters amongst his patients. Mr. Morgan urged Mr.

Harrison in his visits to patients to strive to acquire an attentive anxious politeness, combining ease and grace with a tender regard and interest. This he did so well that within a few months he was supposed, by local gossip, to be engaged to three different ladies at one and the same time. Mr. Morgan was much perturbed and rather peevish at what he thought was Mr. Harrison's mismanagement of affairs, until he found that he himself was reported to be engaged to another lady. There was nothing for it but two sets of wedding bells, and so all ends happily.

The illness of a child and the anxiety which it causes in the village reflects the authoress's experiences of the death of her only son. The book was written some years before *Cranford*, and has the appearance of a prentice hand working at a subject which she later perfected. It introduces, partly as an unintentional mischief-maker, a student friend from London, somewhat of the Bob Sawyer-Ben Allen type.

Cranford is outstanding in literature for its delicate, kindly, and humorous description of the ways of life and foibles of elderly ladies, of aristocratic minds but ill-lined pockets. Into such a society she introduces, as a contrast, a breezy vigorous doctor, who "sups on bread and cheese and beer every night," the genteel society has reason to believe. As a further contrast he is called Mr. Hoggins, probably to emphasize the shock to the society's ideas of propriety when the wolf got into its fold and won the hand of its only titled lady, the widow of an impoverished Scotch baron. Not much is seen of Mr. Hoggins's practice, the main character in the book being the elderly Miss "Matty" Jenkins—and what character in literature can compare with her, with her simple, child-like faith, her trustful nature, and her genteel expedients to eke out her small income, nearly all lost for a time?

Her finest doctor character is Dr. Gibson in her most finished—but, alas! unfinished—work, *Wives and Daughters*. The scene is again Knutsford and neighbourhood. The late Sir Adolphus Ward, Master of Peterhouse College, Cambridge, wrote of the book:

"In *Wives and Daughters* Mrs. Gaskell's later manner asserts itself with genial amplitude and with irresistible grace and ease, ranging from the most charming playfulness of humour to a pathos which softens, subdues, and endears. Were it a fragment, it would be invaluable for its beauty; but, complete as it is, to all intents and purposes, it can hardly be refused recognition as Mrs. Gaskell's masterpiece."

Much of the book is about the doctor's troubles with the womenfolk of his second marriage, and of the contrast in nature between his stepdaughter and his own child Molly.

Professor George Saintsbury, in his preface to an edition of *Pride and Prejudice*, says:

"In the novels of the last hundred years there are a vast number of young ladies with whom it might be a pleasure to fall in love; there are at least five with whom, as it seems to me, no man of taste and spirit can help doing so. Their names are, in chronological order, Elizabeth Bennet, Diana Vernon, Argemone Lavington, Beatrice Esmond, and Barbara Grant. I should have been most in love with Beatrice and Argemone; I should, I think, for more occasional companionship, have preferred Diana and Barbara. But to live with and to marry, I do not know that any one of the four can come into competition with Elizabeth."

Each man to his fancy, but many a humbler critic must rejoice that the professor did not want Molly Gibson for his true love.

George Sand observed to Lord Houghton shortly before her own death:

"Mrs. Gaskell has done what neither I nor other female writers in France can accomplish; she has written novels which excite the deepest interest in men of the world, and yet which every girl will be the better for reading."

Her life of Charlotte Brontë is one of the masterpieces of biographical writing. She pictures so well the life at Haworth Vicarage, where the three frail sisters worked in a small room, in a house bordered on two sides by an extensive graveyard, with a father so dyspeptic that he had all his meals by himself—and the less he saw of the family the better was he pleased—and a brother who spent most of his time in the nearest public-houses. Who that has seen Haworth Vicarage can wonder that its novels, with the exception of *Shirley*, are so full of gloom and shadow, or can wonder that the three sisters all died of a decline? What a contrast there is between its books and the sunny, cheerful, humorous ones of the Manchester clergyman's home written "by one of the most charming, exquisite writers of English fiction that has ever lived, in grace of her style and the quaintness of her humour reminding one of Charles Lamb," to quote another critic writing in the *Nineteenth Century* (1897).

It is of some interest to know that Charlotte Brontë brought her father to Manchester to consult William James Wilson, one of the founders of the Eye Hospital, about his eyesight.

Mrs. Gaskell has not only left an endearing and abiding memory with Manchester and other readers, but the deep feeling for suffering, shown in all her novels, has been given a practical memorial in Manchester by her daughters, who founded and endowed the Gaskell Nursing Home for the benefit of surgical patients between the hospital and the expensive nursing-home classes.

The portrait of de Quincey is reproduced from A. and C. Black's 4th edition of his writings, and that of Ainsworth from *Chambers's Encyclopaedia of Literature*. The portrait of Mrs. Gaskell was supplied by the Warwick Brookes Studios.

Ireland.

Parliamentary Medical Representation.

Of the four members representing the Queen's University, Belfast, in the new Parliament of Northern Ireland, one, Mr. R. J. Johnstone, M.D., F.R.C.S.Eng., is a medical man. He is a member, and was chairman of the commission appointed by the Government of Northern Ireland to take evidence on the Poor Law system and cognate subjects. He will have the best wishes of the profession, who feel that their interests are safe in his hands. Dr. Morrison, co. Londonderry, who, to everyone's regret, was prevented by ill health from allowing his name to go forward, died during the election.

Mr. Thomas Sinclair, C.B., M.D., F.R.C.S.Eng., Emeritus Professor of Surgery in the Queen's University, Belfast, who has again been returned unopposed as the University representative in the Imperial Parliament, commands the confidence both of the University authorities and of the medical profession in Ulster.

Annual Report of the Rotunda Hospital.

Reference was made in a leading article in the *Journal* of May 18th (p. 916) to the encouraging decline in maternal morbidity in the British Islands during the last twenty years, and it is of interest to note in this connexion the statement in the recently received annual report of the Rotunda Hospital, Dublin, that the percentage rates of morbidity during the year ending October 31st, 1928, fell to 3.3—a "record" in the history of the hospital. This figure was calculated according to the British Medical Association standardization; the corresponding "Rotunda rate" was only 2.1 per cent. The Master of the Rotunda, Dr. Bethel Solomons, remarks that so excellent a result was not obtained in palatial buildings or by any complicated means; he attributes it to the zealous care and loyal co-operation of the medical and nursing staffs. He adds that the hospital was fortunate enough to escape any influenza epidemic, and he thinks this freedom was probably assisted by the exhibition of printed notices in the wards asking husbands and other visitors to refrain from coming when suffering from colds. During the year there were only 69 morbidity cases, of which 33 were associated with operative deliveries, so that only 36 non-operative deliveries were morbid out of 2,346 women admitted to the wards of the hospital and 2,062 confinement cases. A total of 1,717 patients received attention in their own homes, and the number of abnormalities in the extern maternity service showed an increase. Dr. Bethel Solomons remarks that, while this type of case is better treated in the wards of a hospital, some of these patients are found to be too ill to be moved, and it is important, moreover, that students should be taught how

to deal with difficulties under more adverse conditions than are to be found inside a maternity hospital. There has been delay in constructing a proposed new operating theatre on the north side of the institution. It is intended to erect a two-storied building, the ground floor of which will provide the much-needed accommodation for nurses and maids, while the first floor will be devoted to the theatre and sterilizing arrangements. It is hoped to increase the accommodation also for ante-natal patients if an adequate response is received to the appeal being made for financial support. The annual report contains also the usual interesting clinical details and tabular statements; on the gynaecological side the number of plastic vaginal operations was large. For the first time in the history of the hospital a report of the *x*-ray department is submitted, in which the immense value of its services is emphasized.

Tuberculosis Scheme for County Wicklow.

The County Wicklow Board of Health has recommended for the approval of the county council (provided it can be financed without any undue burden on the rates) a tuberculosis scheme in County Wicklow, as outlined by Dr. S. Berry, Local Government Medical Inspector. Dr. Berry said that in County Wicklow there were about 800 cases of tuberculosis, with an annual death rate of between 80 and 90 persons. In the County Home, County Hospital, and Sanatorium 23 uninsured persons were receiving treatment; 24 insured persons were getting institutional treatment. The gross cost of that treatment in the year—not all off the rates—was £1,059, for which 83 cases were treated. They were treating fewer cases in Wicklow than were actually dying from the disease, and their death rate was one of the highest in Ireland. He said a central dispensary could be established in Wicklow town, with branches at Bray, Arklow, Blessington, Newtownmountkennedy, Baltinglass, and Tinahely. These dispensaries would give opportunity to all persons in the county suffering from tuberculosis to obtain treatment from a tuberculosis officer and the services of a skilled nurse. Newcastle Sanatorium could be made available, and circulatory hospitals, such as the Memorial Hospital at Arklow, Wicklow Hospital, and Dublin, could be made available for treating surgical cases. For bad cases Shillelagh Fever Hospital could be utilized.

Antituberculosis Campaign.

At the recent Congress of the Royal Institute of Public Health at Zürich, Sir William Thompson, ex-Registrar-General for Ireland, in his presidential address to the Tuberculosis Section, drew attention to the results ensuing from the antituberculosis campaign initiated in Ireland in 1906. He stated that in the Free State there were 4,138 fewer deaths from tuberculosis in 1928 than in 1906, and that there were 40,000 to 50,000 fewer persons suffering from the disease. He drew attention to the important work of the National Health Association in Ireland.

Health Statistics in Northern Ireland.

During the quarter ending March 31st, 6,324 births were registered in the twenty-seven Superintendent Registrars' districts in Northern Ireland, this number representing an annual birth rate of 20.2 per 1,000 of the estimated population. The comparable figure for England and Wales is 21.0, and for Scotland 21.9. The rate in Northern Ireland is 0.8 below that for the corresponding quarter in 1928, and 2.6 below the average rate for the first quarter of the ten years 1919 to 1928. The deaths registered during the quarter numbered 7,708, or an annual rate of 24.7 per 1,000 of the estimated population. This rate is 7.6 above that for the corresponding quarter of 1928, and 5.5 above the average rate for the first quarters of the ten years 1919 to 1928. The urban mortality from the principal epidemic diseases recorded during the quarter was equivalent to an annual rate of 1.4 per 1,000 of the population, comparing with a figure of 0.4 for the remainder of Northern Ireland.

Cinematographic Demonstration.

The president and council of the Leinster Branch of the British Medical Association have issued invitations to members and non-members of the Association to be present at a cinematographic demonstration of living tissue cells cultivated *in vitro*, including the action of radium on them, to be given by Dr. R. G. Canti (St. Bartholomew's Hospital), in University College, Earlsfort Terrace, Dublin, on Friday, June 14th, at 8.15 p.m.

Scotland.

Reconstruction of Edinburgh University Medical Buildings.

REFERENCE was made in the *Journal* of May 11th (p. 879) to the decision to reconstruct the University New Buildings in Teviot Place, Edinburgh, at a cost of £60,000. It has now been announced that promised gifts for this purpose include one of £35,000 from the Rockefeller Foundation, and another of £20,000 from Sir William Dunn's trustees, making a sum of £55,000 in all. This, together with other money which is available, now secures the carrying out in its entirety of a scheme drawn up by the architect, Mr. Balfour Paul, in consultation with the heads of the departments concerned, and the work will be begun in the summer vacation. The external aspect of the buildings, erected in 1880 from designs by the late Sir Rowand Anderson, will remain unaltered. Certain portions of the reconstructed building will in future be associated with the name of Sir William Dunn in recognition of the generous gift from his estate.

Puerperal Pyrexia in Aberdeen.

The report on the incidence of puerperal pyrexia in the city of Aberdeen during 1928, included in the annual report of the medical officer of health, is worth studying in connexion with the official document issued by the Scottish Board of Health on maternal mortality in Aberdeen, 1918–1927,[1] which was the subject of an article in our columns on January 12th (p. 79), and of editorial comment on January 19th (p. 115). During the year 73 cases of puerperal pyrexia, of which, however, 25 were found to be due to bacilluria, pyelitis, mastitis, etc., were notified as having occurred in the city. Of the remaining 48 cases of true puerperal sepsis, 8 occurred in the practice of midwives, with 1 death; 21 in the practice of medical practitioners, with 4 deaths; and 19 in the practice of public institutions, with 5 deaths. Forty-three cases were treated in public institutions and 5 at home. In 7 of the cases pregnancy terminated in abortion, with a fatality in only 1 case. In January an outbreak of septicaemia occurred in a maternity institution with twenty maternity beds and eight beds for ante-natal cases. On investigation it was found that twelve mothers had developed puerperal fever within a period of five weeks, and that four had died, two with other grave puerperal complications. Bacteriological examination proved the outbreak to be due to haemolytic streptococcal infection. At the same time there was an outbreak of icterus neonatorum, which resulted in the deaths of seven infants; in two of these cases post-mortem examinations were carried out and the cause of death was shown to be septicaemia due to *Streptococcus haemolyticus*. Some seventeen mothers who had been in contact with the cases of puerperal sepsis were subjected to bacteriological examination. Haemolytic streptococci were isolated from both the uterine and throat cultures of one of the contacts, from the uterine cultures of four contacts, and from the throat cultures of three others. Throat cultures obtained from the staff of twelve nurses gave positive results in five. It was not possible to determine the original source of the infection, though the admission of a case of septic abortion just before the outbreak was regarded with suspicion. Unfortunately the infection had spread and the outbreak was fully developed before the intervention of the health department was able to put an end to it. The Aberdeen statistics of puerperal sepsis indicate that in the institution concerned similar outbreaks of puerperal sepsis, spread by gross contagion, had occurred in 1922 and in 1924.

Sanitation and Health.

At the annual conference of the Sanitary Inspectors' Association held recently at Paisley, Mr. Allan Ritchie, chief sanitary inspector, Edinburgh, gave a presidential address on the Chadwick outlook, surveying this pioneer sanitarian's influence. The records, he said, showed wonderful achievements in the past fifty years, during which the death rate had been halved. Some infectious diseases, which carried off thousands half a century ago, were now almost unknown. Children had a better chance of life, and there was less tendency to ill health in later life. The speaker was convinced that the real major health services of the present day were not so much hospitals and clinics as well-constructed sanitary dwellings, open spaces with sunlight, plentiful water supply, good food, and playing fields. Slum clearance must be one of the main efforts of the future. The purity of water and milk supplies had now reached a very high level, but it was also important that high standards should be reached in purity of food and air supplies, which at present showed far too much avoidable contamination. He thought that it was surely time that more strenuous efforts were made to prevent the smoke screen which hindered the action of health-giving rays.

Harveian Festival at Edinburgh.

The one hundred and forty-second Harveian Festival was held in the Royal College of Physicians of Edinburgh on May 31st. This year's president of the festival, Dr. Lewis Bruce, M.C., of Murthly, delivered the oration on "Life and Customs in the Time of William Harvey," drawing a graphic picture of domestic and social customs and of political events in the seventeenth century. At the banquet which followed a number of neophytes were initiated. The toast of "The Immortal Memory" was proposed by the president, and the minutes of the previous year's proceedings were read by Mr. J. W. Dowden. Dr. Douglas Miller proposed the health of the guests, and a reply was made by Lieut.-Colonel J. Cunningham, C.I.E., a son of the late Professor D. J. Cunningham, who has recently been appointed to the post of superintendent of the Astley-Ainslie Convalescent Institution in Edinburgh. The president's health was proposed by Dr. Derek Melville Dunlop. It was announced that next year's president would be Professor G. Lovell Gulland.

Central Midwives Board for Scotland.

At the examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, just concluded, out of 154 candidates who appeared for examination 133 passed. Of the successful candidates, 23 were trained at the Royal Maternity Hospital, Edinburgh; 55 at the Royal Maternity Hospital, Glasgow; 7 at the Maternity Department, Royal Infirmary, Dundee; 4 at the Maternity Hospital, Aberdeen; 16 at the Elsie Inglis Memorial Hospital, Edinburgh; 6 at Stobhill General Hospital; 6 at the County Maternity Hospital, Bellshill; 6 at Barshaw Maternity Hospital, 2 at the Eastern District Hospital, 2 at the Western District Hospital, Glasgow; and 2 at the County and City of Perth Royal Infirmary.

England and Wales.

Medical Education in South Wales.

THE long dispute between the Welsh National Medical School and the Cardiff Royal Infirmary came to an end on May 29th, at a fully representative meeting of the Infirmary board of management, when an agreement between it and the Cardiff College and Welsh National University authorities was accepted unanimously. For some time a draft scheme of co-operation has been under consideration, and its salient points were indicated in our issue of December 29th, 1928 (p. 1187). There were many difficulties to be overcome, and the final agreement, which contains twenty-four paragraphs, is in some degree a compromise, a fact which indicates the highly commendable desire on both sides to yield as far as may be legitimate in order to bring to a close a period of uncertainty and disorganization which has lasted about twelve months. It is now agreed that the medical school shall be conducted on the "unit system," and have at its disposal for clinical teaching all the existing beds of the Infirmary. Each professorial unit or clinic will rank as one of the hospital clinics or firms. Beds are to be allocated to the University professors of the College, who thereby become honorary members of the Infirmary staff, the professor of medicine receiving thirty beds, the professor of surgery forty-six, and the professor of obstetrics and gynaecology eleven. The professor of pathology, on appointment, will similarly become an honorary member of the Infirmary staff and an honorary pathologist to the institution enjoying facilities at the Infirmary for the necessary pathological work in connexion with the teaching. A board of clinical studies is to be formed, consisting of all the recognized clinical teachers and part-time lecturers who are members of the honorary medical staff of the Infirmary; the lecturers in radiology and anaesthetics, together with the professors of medicine, surgery, obstetrics and gynaecology, and pathology; and such other teachers as may be recommended by the board and approved by the authorities of the school. The board will organize the clinical teaching of the non-professorial clinics at the Infirmary to conform to the regulations and courses of study required for the degrees and qualifications of the University of Wales and other licensing bodies. It will have the right of direct access to the board of medicine and will be able to report to it on any important matter connected with the clinical teaching at the University. One practical difficulty has been settled by making a change with regard to appointments—especially of senior assistants—and arranging for their due recognition as members of the staff of the hospital. The agreement had been previously approved by the councils of the University College and University; its ratification by the Infirmary board, therefore, completed the necessary formalities, and it is hoped that the school will now be able to open its doors again to all classes of students in September and resume its interrupted development.

Professor Wardrop Griffith.

The Court of the University of Leeds has recommended the conferment of the honorary degree of doctor of science on Dr. T. Wardrop Griffith, who was professor of anatomy in the University from 1887 to 1910, professor of medicine from 1910 to 1925, and representative of the University on the General Medical Council from 1918 to 1927. Dr. Wardrop Griffith graduated M.B., C.M. in 1882 at the University of Aberdeen, and proceeded M.D. in 1888; the honorary degree of LL.D. was conferred upon him in 1922. On graduation he was appointed demonstrator of anatomy and, subsequently, resident medical officer to the General Infirmary at Leeds; he joined the honorary staff in 1892 and was elected full physician in 1905, becoming a member of the consulting staff twenty years later. He is also consulting physician to the Leeds Public Dispensary. During the war he was stationed at the 2nd Northern General Hospital, and was promoted brevet lieut.-colonel in 1918; he was honorary consultant on cardiac affections for Yorkshire to the Ministry of Pensions. In 1918 he received the honour of Companionship of the Order of St. Michael and St. George. He is the author of numerous articles on diseases of the heart and circulatory system.

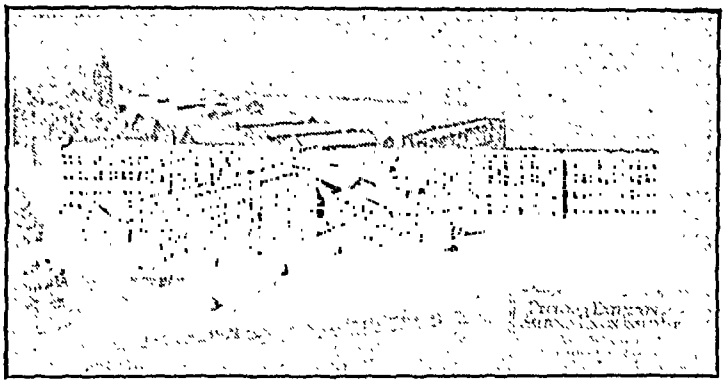
University College Hospital Medical School.

With the close of the academic year 1927–28 University College Hospital Medical School has completed one hundred years of its existence, first as part of the medical faculty of University College, and then, for the last twenty-one years, as a separate school for advanced medical studies controlled by the corporation of University College Hospital. The dean, Dr. A. M. H. Gray, records in his annual report that during the session the total entry of students was 152, of whom fifty were students taking the full course; and that the total number of students in attendance was 269. The construction and rearrangement of the wards in the hospital is now completed, making some 520 beds available for clinical instruction. Of these, 415 beds (357 allocated to adults and 58 to children) are in the main general hospital, 75 in the obstetric hospital, and 31 (20 for adults and 11 for children) in the Royal Ear Hospital. There

are beds specially set aside for the treatment of skin cases, venereal cases, tuberculosis, ophthalmic cases, and neurological and psychological cases. The new clinical laboratories, which have been formed by the reconstruction of the old operating theatres in the hospital, are ready for use. All floors in the central block of the hospital have been reconstituted, and on each of the first, second, and third floors a large central clinical laboratory has been built, with two smaller rooms annexed for special work. These groups of laboratories, which serve the wards (four on each floor, with which they are in close relation), have been allotted two to the medical department and one to the surgical. On the fourth floor has been established a central record room, with side offices for the medical and surgical registrars. The addition of these laboratories not only renders possible routine and special clinical investigations by the students and resident officers without interference with the more advanced work carried out by the clinical pathologist, but it allows of pathological demonstrations to be combined with ward visits in a way that was not previously attainable.

Extension of Salford Union Infirmary.

Plans have been approved for the extension of the Salford Union Infirmary, situated at Pendleton on a secluded spot overlooking a stretch of country towards Worsley. The original building, erected nearly fifty years ago, can no longer meet the needs of the city, whose population is now about a quarter of a million, and the pressure on its accommodation in recent years has been so great that extension has become imperative. The new building, for which the proposed schemes have been sanctioned by the Ministry of Health, will contain 1,500 beds, as well as 500 beds in adjoining buildings for the use of aged and infirm persons. It will comprise a children's hospital, wards and theatres for the treatment of surgical cases, accommodation for paying patients, *x*-ray rooms and a radiological treatment room, and a separate block of buildings for the nursing staff. The wards have been designed to admit the maximum amount of sunlight, and each block will have a flat roof to which patients can be easily moved to enable them to benefit by fresh air whenever the weather permits. On the ground floor are examination rooms for both sexes, with bathrooms attached; there is a separate entrance for patients, with a covered portico for ambulances. The radiological department is situated on the ground floor, and comprises two *x*-ray rooms and dressing rooms, a waiting hall, a dark room, and a film-viewing room; there are also two diathermy and *x*-ray treating rooms, and a sunroom. In the basement is accommodation for the storage of electrical apparatus connected with the *x*-ray instruments, so as to avoid any noise being heard during treatment. Two large operating theatres, facing north, occupy the ground floor of the operating block; one of these can be darkened for special ophthalmic and other operations. The new buildings will be connected to the existing hospital by extension of the corridor at the western end. This new addition constitutes only a part of the contemplated scheme, which will eventually comprise a children's hospital, accommodation for the treatment of acute surgical cases, sufficient room for the reception of paying patients, and, in conjunction with the existing buildings, which contain 850 beds, will provide for the treatment of all other cases of sickness and accident for which public hospital accommodation may be necessary. The existing separate accommodation for a nursing staff, numbering about 250, will be extended to meet the additional requirements. The hospital will serve the city of Salford only, when the Local Government Act, 1929, comes into force.



PROPOSED EXTENSION OF SALFORD UNION INFIRMARY.

National League for Health, Maternity and Child Welfare.

The National League for Health, Maternity and Child Welfare, which went into voluntary liquidation in order to facilitate a certain measure of reorganization required by the Carnegie Trustees, came to an end on December 31st last. It has transferred all its functions and its assets to its two daughter societies—the Association of Infant Welfare and Maternity Centres, and the National Association for the Prevention of Infant Mortality. In its report for the year ended December 31st, 1928—the last it will publish—is included a general survey of the league's activities since the date of its foundation in 1905. The league began life under the title of the National League for Physical Education and Improvement, with the aim of uniting all existing associations and societies devoted to child welfare, the training of children and youths, and strengthening the population physically, mentally, and morally. From the first it found itself obliged to promote legislation in aid of its objects, and in 1905, having failed to secure from Mr. Birrell, then President of the Board of Education, a promise to incorporate provision for the medical inspection of school children in the new Education Bill, it devoted itself to propaganda work, aimed to this end, which culminated in 1907 in the passing of the Education (Administrative Provisions) Act. The necessity for obtaining a pure milk supply was urged by the league from 1906 onwards, and in 1910 it inaugurated a clean milk campaign, which prepared the way for the passage of the Milk and Dairies Act in 1915. By the passing of the *Fabrics (Misdescription)* Act in 1913, the league, single-handed, secured legislation to minimize the loss of life due to the wearing of inflammable makes of flannelette. It played an active part in promoting the Maternity and Child Welfare Act, 1918, and the Ministry of Health Act, 1919. In pursuance of its policy to co-ordinate societies having aims similar to its own, it succeeded in 1917 in uniting in a single federal movement no fewer than nine societies to form the National League for Health, Maternity and Child Welfare. Among the subjects investigated and reported on by the league may be mentioned health visiting, infant welfare centres, organized play, sick clinics, open-air clinics, ante-natal clinics, artificial light clinics, and dental clinics. In 1914 and throughout 1915 workers trained by the league, acting in co-operation with the local health authorities, succeeded in starting 154 new infant welfare centres, of which 27 were entirely municipal; in 1915 it initiated six experimental ante-natal clinics, and in the same year it set on foot an extensive anti-fly and vermin campaign; in 1918 it opened the still flourishing residential home for babies of the middle class whose mothers were dead or whose fathers were unemployed after the war. Four maternity homes set up by the league are actively engaged in good work. Other ventures have been the establishment in 1919 of a small nursing home for mothers with babies, in 1920 of the Tired Mothers' Holiday Fund, and in 1922 of a guest house for mothers with young babies. The National League has come to an honourable end, full of vigour and good repute, and solvent.

School Medical Inspection in Bournemouth.

Dr. H. Gordon Smith, in his annual report for 1928 as school medical officer for Bournemouth, remarks that there appears to be evidence of an increasing influence for good during pre-school life, since the proportion of entrants found to require treatment in 1928 was 10 per cent., as compared with 12 per cent. for the previous year. He attributes this to the work of the maternity and child

welfare centres. Similarly, the percentage of those leaving school who require treatment has dropped from 17 to 15, and the school medical service seems to be responsible for this improvement. Dr. Gordon Smith emphasizes the point that a serious gap exists in the care of the health of children during the two or three years before they enter school, and regrets that the nursery schools foreshadowed by the Education Act of 1923 have not yet materialized. Many children admitted at the age of 5 have physical defects which could have been either prevented or cured. A certain amount of the defective vision of children is thought to be due to inadequate window space and placing in some schools, where such defects have been found to be more common than in the better planned and more hygienic schools; regrouping of desks will not solve the difficulty, in Dr. Gordon Smith's opinion. The rarity of rickets in Bournemouth is attributed to the large amount of sunshine, purity of the atmosphere, the number of parks and open spaces, and the housing, which is for the most part good. There has also been improvement in the spread of knowledge about diet and general health matters. Children wishing to be employed out of school hours are examined by the assistant school medical officer with reference to their physical fitness to undertake work. In all satisfactory cases certificates are granted stating that the employment will not be prejudicial to the child's health or physical development, and will not interfere with education. The children are also examined at the request of the Juvenile Employment Committee with regard to their physical fitness to undertake a specified employment on leaving school.

Correspondence.

THE CLEVELAND DISASTER.

SIR,—The *X*-Ray and Radium Protection Committee met this afternoon under the chairmanship of Sir Humphry Rolleston. It is the intention of this committee, as further facts reach it, to pursue investigation into the whole question of possible danger from *x*-ray films, and to draw up such recommendations as are considered advisable.

In the meantime, the committee makes the following common-sense suggestions:

1. Care should be taken to ensure that *x*-ray films, whether exposed or unexposed, are stored and handled in such a manner as to reduce to a minimum the danger of fire.

2. Films should not be left lying about, but should be stored in filing cabinets or cupboards in such a way as to limit the number of films actually lying open during reference.

3. On no account should smoking or naked lights be permitted in proximity to any film store.

4. In the case of large hospitals or institutions where considerable numbers of films may be accumulated, a special store, preferably isolated, should be arranged solely for such films.

—We are, etc.,

SIDNEY RUSS,
STANLEY MELVILLE,
Honorary Secretaries.

London, W.1, May 29th.

"YEAST AND PUFFERY."

SIR,—I observe a paragraph in your issue of April 27th (p. 760), headed "Yeast and puffery," in which I am greatly interested.

I presume that this paragraph refers to advertisements which are appearing every week in some thirty to forty magazines and periodicals published in the United States and in Canada. I enclose one of the last I have seen, published this month, "featuring" a medical man of repute in Great Britain who, I had imagined, could not possibly have been guilty of such bad judgement.

I may say that great pressure was brought to bear on me to allow my photograph and opinion to be published as an advertisement to further the interests of this business concern. A considerable sum of money was offered in payment. Needless to say, I declined.

Because of the numbers of prominent men in various parts of the world who have allowed their names to appear already, or in future issues of these periodicals, I am tempted to ask, "Have the ethics of our profession changed?"

From my point of view it seems reprehensible to prostitute the good reputation of the profession by any of its members sanctioning the use of their names for commercial purposes. Of course, it is a cheap way to earn notoriety, but it leaves a nasty impression, even if only because everyone knows that such advertisements are paid for. As your paragraph indicates, right-thinking people regret to see such "puffery," which brings the profession into ridicule. Where will it end? The names and reputations of those who had yielded to temptation were used as a lever to try to get me to yield also. "If these famous men have done it, why should not you?" I will not insult the general practitioner, be he town or village doctor, by suggesting that he may now be influenced by bribes from his grocer or butcher to give his name in support of locally made candy or sausages, and so forth. But the difference is only in degree.

I feel, further, that this trafficking for support of specialists of repute by business concerns for their own gain will, unless it is nipped in the bud (already a large one), be disastrous to the interests of the public for whom the medical profession has assumed health guardianship, and will be equally disastrous in the dishonour accruing to that profession.—I am, etc.,

Montreal, May 21st. HENRY M. W. GRAY.

PUERPERAL SEPSIS AND THE GENERAL PRACTITIONER.

SIR,—I have been ten years in private practice. My practice is of the mixed town and country kind, and includes all classes. In the ten years I have attended 550 maternity cases. My experience may be worth relating, as it includes cases attended in the maternity ward of the Westmorland County Hospital, in a nursing home, and in private houses. My patients include an abnormal proportion of difficult cases transferred by other doctors.

I have notes of six cases of puerperal sepsis, and they present features which call for explanation.

Case 1.—The baby was born before the arrival of doctor or nurse. The patient was a multipara. There had been no examination and no laceration. She was removed to hospital; nothing was found in the uterus, and this patient, after a long period of pyrexia, eventually recovered.

Case 2.—This case was delivered in a nursing home. A multipara, she delivered herself without intervention by doctor or nurse, the baby being born as I entered the room. In this case the patient had a slight cold and a temperature of 99° on admission. On the third day she had a rigor; her pulse and temperature rapidly rose, and the case soon presented all the features of a virulent septicaemia. This case terminated fatally after developing multiple pyaemic abscesses.

Case 3.—I was asked to see this case by a colleague. He told me that the baby was born in the house before he arrived, and he was met at the door by a hysterical patient, carrying the baby in her arms, and the placenta *in situ*. She was removed to a nursing home, the temperature when I saw her on the fifth day being 104°. Examination revealed a hard band of thrombosed veins, stretching, in the base of the left broad ligament, from uterus to pelvic wall. No laceration was found in the cervix and nothing in the uterus. Again, after a prolonged period of pyrexia, this patient recovered. In her case septic tonsils and bad teeth were both present.

Case 4.—This case I was asked to see by a colleague in a remote country practice. It was a forceps case conducted in a farmhouse. The temperature rose on the third day, and when I saw the patient she presented a picture of septic infection. She was removed to hospital. No laceration was found, and nothing retained. A catheter specimen of the urine was obtained; pus was found in it, and culture showed it to be heavily infected with *B. coli*. This patient eventually made a good recovery.

Case 5.—This was a bad case of total placenta praevia, transferred to me by a colleague. Repeated haemorrhages had taken place, and, in view of the fact that the mother was an elderly primipara and rather small, it was decided that Caesarean section offered the best chance for both mother and child. The vaginal examination was made in the home under strict surgical precautions, and the vagina and cervix were cleaned with spirit and iodine before operation. The operation was performed at 11 a.m. I should say that the patient was a week under observation, and no temperature was recorded before operation. At 6 p.m. the

temperature was 102°, and she ran a temperature for five weeks, developing a pyaemic abscess in the left thigh. The uterus involuted normally, and the wound healed by *first intention*.

Here was a case where, clearly, an infected clot had been disturbed in separating the placenta, and septicaemia resulted. The obvious conclusion, in the light of present teaching, is to say that the placental site had been infected from without. Well, it may have been, but I doubt it. Examination was conducted under the strictest precautions, the placenta could not be felt through the cervix, and, in view of the fact that the teeth were in a very septic condition, I have little doubt that they were the cause of the trouble.

Case 6.—This case is at present under my care in the Westmorland County Hospital. Again the baby was born before I arrived, and no examination had been made. On the third day the patient had a rigor, and rapidly presented the picture of an acute septic infection. Nothing was found in the uterus on examination, but a catheter specimen yielded a urine heavily loaded with *B. coli*, and containing a few round and epithelial cells. Here we have to deal with, apparently, a *B. coli* infection of the kidney, although the patient did not complain of the lumbar pain so commonly associated with that condition. She, too, is making a good recovery.

Now the present teaching is that puerperal sepsis is a *preventable disease*. We are told that if all births were conducted on strictly surgical lines under good conditions puerperal sepsis should not occur, and the practitioner of to-day is roundly accused of incompetence and of not knowing his job. In other words, the dictum is that sepsis is introduced from without.

I have mentioned my cases of puerperal pyrexia and septicaemia. They are few in number, but each tells a story of infection from within. What of the cases I have *successfully delivered under bad conditions*? I have one case in my mind where I delivered with forceps a small woman of four living children in a farmhouse, under hopeless conditions from the point of view of maintaining surgical asepsis. Why, why does such a case not go septic? Again, I have twice performed that dreadful operation craniotomy in country cottages, when I was called in to find the patient had been many hours in labour, the water drained away, and a face presentation impacted in the pelvis in one case and the head above the brim in the other.

Time and time again, if infection were brought from without, as we are taught, I have had cases which should have developed sepsis, the type of case with which every practitioner is familiar, where there are a deficient water supply, bad light, insanitary conditions, and inadequate help. Why not?

Again, we are told that maternal mortality has remained constant in spite of the advance in medical science. Now *no one will deny that the medical man of to-day is much* more surgically clean in the conduct of his cases than his predecessor *of forty years ago. Surely, if the doctrine* of infection from without is true, we should have seen some *indication in the mortality figures. Does the experience* of surgery offer any clue to the source of infection in puerperal sepsis? I have *operated on 150 cases of acute* appendicitis in the last three years. In that series I have had two cases complicated in convalescence by a virulent infection of the kidney with *B. coli*, obviously a haematogenous infection. Here we have a blood infection arising from a focus of local sepsis, and, curiously enough, it closely agrees with my percentage of puerperal sepsis, suggesting a haematogenous origin of puerperal sepsis.

No, as a general practitioner I feel we are not getting fair treatment. If the doctrine of infection from without were true the mortality figures would be vastly higher, and I further believe that teeth, tonsils, and bowels are responsible for more puerperal sepsis than ever resulted from unskilled examination.

We shall not reduce puerperal sepsis by talking piously about improving the education of the general practitioner and providing more and better nurses. By all means let our professors and mentors pursue those laudable objects; but they have been doing so for twenty-five years with no result discernible in statistics. But if a "humble" general practitioner may presume to suggest, let us concentrate on ante-natal work, abolish septic teeth, septic tonsils, and constipation. Let us provide the necessary accommodation and care for the difficult cases in hospital, and I venture to say that the remainder, if healthy at the time of delivery, will take no harm even under the worst of home conditions.—I am, etc.,

Kendal, May 20th. COLIN M. CRAIG, M.D., D.P.H.

ANTE-NATAL CARE.

SIR,—The able article by Sir Henry Simson on maternal mortality in childbirth, in the *Journal* for May 11th (p. 869), should do a great deal of good. But will it? No; for the simple reason that, speaking generally, women are wholly ignorant about ante-natal care. The one thing needful is to tell all women (and men) quite plainly that the time to see the doctor is before the confinement and not at the last minute.

It is cruel that this life-saving care is within the reach of every woman and yet entirely concealed by the mysterious and repellent name of "ante-natal clinic." Women do not know what this means. The general public has the vaguest ideas about ante-natal care, birth control, and abortion; it imagines they are all one and the same, and a rather doubtful proceeding. When we talk plain English and call them by some simple and attractive name, such as centres (or welcomes) for expectant mothers, women will understand at once and ask for advice. I have been for years past telling all women I meet about this; and I find that all classes are ignorant about it and very thankful to learn.

About a year ago, at the Royal Society of Medicine, a speaker raised a laugh by a casual allusion to some colonial officials who thought ante-natal care "was Marie Stopes's ideas." I did not laugh, for I understood at once that the same confusion between "ante" and "anti" is in the minds of many in this country; they hear the word ante-natal and they think it must mean birth control, which many people imagine to be abortion.

This is a matter of national importance; the welfare of the mothers of the nation is at stake. Let us drop our Latin and speak the common tongue, understanded of the people, as the Prayer Book says. Let the less wealthy mothers know that maternity benefit depends on seeing the doctor before the confinement, and let all the general public see and understand what maternity hospitals are like. We shall then get the confidence of the mothers (and fathers), and trust will replace the present miserable apprehension and secrecy.—I am, etc.,

May 28th. P. W.

GALL-STONES AND PREGNANCY.

SIR,—In his interesting address on "The woman damaged by child-bearing," published in your issue of May 18th (p. 891), Dr. James Young refers to the supposed influence of pregnancy on gall-bladder disease. It is true that gall-stones are found with equal frequency in men and in childless women, and that for every childless woman with gall-stones there are four women with gall-stones who have had one or more children. But, as I pointed out in an address on "The constitutional factor in disease," which you published on May 7th and May 14th, 1927, it is also necessary to remember that about four women out of every five have one or more children before they die. It follows that, apart from any special liability to the disease, four women who have had children will have gall stones for every one woman who has had no children. The relatively much greater incidence in women than in men cannot therefore be due to the hypercholesterolaemia of pregnancy.

My views on the subject have been recently confirmed by Dr. Desirée Gross from the Leeds post-mortem records.* She found that 89.7 per cent. of 218 women over 25 with gall-stones were married, compared with 87.2 per cent. of 626 women over 25 without gall-stones; and whereas only 7.1 per cent. of 5,319 men had gall-stones, 21.5 per cent. of 106 single women and 27.6 per cent. of 739 married women had gall-stones. Statistically the small differences between the single and married women are of no appreciable importance.—I am, etc.,

New Lodge Clinic, Windsor Forest, May 26th. ARTHUR F. HURST.

* Dr. Gross's paper on the subject will shortly be published in the *Journal of Pathology*.

EPHEDRINE IN ASTHMA.

SIR,—The report in the *Journal* of May 25th of the Royal Society of Medicine's discussion on ephedrine (p. 954) prompts me to record the results that I have obtained from the study of a series of forty-eight patients suffering from asthma treated by this drug. The cases were entirely unselected, except that the great majority were obtained from "hospital practice." The period of trial varied from a few weeks to fifteen months, and the dosage from gr. 1/4 b.d. to gr. iii t.d.s. The cases can be divided into five groups according to the degree of response to treatment, as follows.

Group A: 13 cases (27 per cent.), in which the drug was employed with unqualified success, the patients being absolutely free of attacks whilst taking the drug. The fact that in five of these cases discontinuance of the drug was followed by recurrence of symptoms—the period of trial extending in each case for more than five months excluding coincidence as a plausible explanation, and the fact that only one of these patients was an adult making a psychological explanation untenable—points in no uncertain way to the efficacy of ephedrine in these instances.

Group B: 13 cases (27 per cent.), in which the benefit was most marked, an occasional attack (of modified severity) breaking through the barrage of the ephedrine defence, causing this group to be separated from the first group.

Group C: 4 cases (8.5 per cent.), in which only slight benefit was obtained.

Group D: 5 cases (10.5 per cent.), in which the issue was inconclusive.

Group E: 13 cases (27 per cent.), in which there was no apparent benefit.

These results are distinctly less flattering than those reported in the American literature.

Twenty-six of the total number of patients were children of 12 years and under, and it is interesting to note that these are proportionately represented in each of the groups. Neither the frequency nor the severity of the attacks seemed to afford the least clue as to the benefit that might be expected from the employment of the drug, excepting that in those attacks that resisted an injection of adrenaline ephedrine was equally powerless. Seven patients complained of symptoms referable to taking the drug. Three complained of sleepiness, one only of insomnia, two of vomiting (one severe), and one of nervousness, sweating, and palpitations. Only in one case was it necessary to discontinue the drug, while in only one of the nine patients in Groups A and B who were treated for a period of longer than six months was there any suspicion of acquired tolerance.—I am, etc.,

E. G. RECORDON,
House-Physician, St. Bartholomew's Hospital, E.C.1.

May 29th.

THE HOLLOW SURGICAL NEEDLE.

SIR,—In surgery, as in other arts, useful methods and practical devices may come into being, be practised sporadically and intermittently by the individual, and fall into disuse "unwept, unhonoured, and unsung." Among such is the hollow surgical needle. In principle it lays no claim to recent invention, for it has long been adapted to serve special branches of surgery; furthermore, it materialized many years ago in the form of a hollow needle for general purposes, but this has never found its way into the routine of daily surgery.

It is to the general practitioner that the use of the hollow needle is most likely to commend itself. The operating surgeon might find it of use, but will probably reject it as an encumbrance to his armamentarium, for he usually operates on patients under general anaesthesia: the question of pain does not concern him, therefore, and further, he does not run the risk of coming face to face, in his daily rounds, with an almost invisible wound cicatrix flanked by a double row of very obvious suture scars. Thus, in his case, the *raison d'être* of the hollow needle practically vanishes.

In your issue of April 8th, 1905 (p. 808), you published a letter from Dr. Gubb advocating the use of a hypodermic syringe needle for the insertion of superficial wire sutures. The advantages claimed for the device, as compared with the method in current use, were that the pain of insertion was reduced to that of a hypodermic needle puncture, and that there was no scarring, such as results from the incision made by the cutting edge of an ordinary suture needle. Shortly after I read the letter a child with a split lip was brought to me; I closed the wound with a suture inserted in the manner suggested, using, however, horse-hair instead of wire.

In recent years I have often had to treat superficial wounds of conspicuous parts without a general anaesthetic. This revealed the need of a curved hollow needle, since a straight one is useless when the wound is situated in a sulcus or depressed part of the surface. I submitted the problem to Messrs. Allen and Hanburys, suggesting a hollow, semicircular needle, about 1 in. in diameter and without a cutting edge. Shortly afterwards I received samples in three sizes—1 in., 1⅛ in., and 1¼ in. in diameter—the larger ones carrying a somewhat heavier suture than the smaller. I now have a supply of these needles, which I keep ready threaded with horse-hair or silkworm-gut, and immerse such as I am about to use in a solution of iodine or mercurochrome. Incidentally, I have never seen stitch sepsis occur in connexion with these sutures—a result probably due to following Dr. Bernhardt's practice of exposing wounds to the air—for dressings render the subjacent tissues weak and soggy, thereby furnishing a soil favourable to the growth of vegetable organisms, which are further encouraged to germinate by the induced warmth and moisture of their surroundings.

The procedure recommended is as follows:

Paint the skin area for a suitable distance around the wound with a 2 per cent. solution of mercurochrome—an antiseptic that does not cause smarting. Apply wool soaked in apothesine or other cocaine derivative to the raw surface of the wound. Pick the needle out of mercurochrome with artery forceps or needle holder. Withdraw the suture till the end is within the eye of the needle. If more than one suture is necessary, work from the middle of the wound towards the ends. Introduce the needle on that side of the wound where the skin is more mobile, and let it emerge on the more fixed side

When the point of the needle emerges, push the suture through it from the other end and pull through a sufficient length on the distal side to tie. Withdraw the needle from the tissues and along the suture till there is sufficient length on the near side to tie. Cut the suture at the point of the needle, so that this remains threaded ready for the next stitch. Secure accurate apposition and tie. Proceed with the next suture, remembering always to introduce the needle on the more mobile side of the wound and to let it emerge on the more fixed side—a direction which may be reversed in successive stitches. After the patient has recovered from the first shock of the injury, rest or not is prescribed according to the position and severity of the lesion. Paint the wound area daily with mercurochrome and remove the stitches on the fifth day.

The advantages of the hollow needle are those mentioned thirty years ago by Dr. Gubb.

There are one or two general principles incidentally involved in the suturing of wounds which it may be of use to mention. It is good practice to lubricate all instruments used to puncture or cut living tissues. Blood should be thoroughly removed from parts away from the wound but not from the bleeding surface itself, where it plays an important part in the process of repair. As it issues from the vessels blood is aseptic, it helps to promote union by gluing wound surfaces together, while a continuous scab maintains intimate approximation along the line of contact of wound edges. By clotting it tends to arrest haemorrhage and affords a stroma for the development of cicatricial tissue. The sutures serve to arrest haemorrhage from more important vessels, and to squeeze out any excess of blood which may be present between wound surfaces.—I am, etc.,

STUART TIDEY, M.D., M.R.C.P.

London, W.14, May 18th.

APPENDICITIS AS A COMPLICATION OF BILHARZIAL INFECTION.

SIR,—In your issue of May 4th (p. 810) a memorandum by Dr. H. E. Harris records a case of appendicitis, presumed to be caused by the presence of bilharzia ova in the organ, as an unusual occurrence.

We would take the opportunity of indicating that the deposition of bilharzia ova in the appendix is far from uncommon in Egypt. In over 50 per cent. of the appendices removed at operation for subacute or chronic

appendicitis and submitted to us for histological examination we find a similar picture to that described in the note in question. In several cases enormous numbers of ova are demonstrable in every field of the microscope, and completely encircle the glandular layer of the organ. It is questionable, however, whether the inflammatory process is due in all cases to the presence of these sources of irritation.—We are, etc.,

Public Health Laboratories, Cairo, May 23rd. H. MARRIAN PERRY. HAROLD J. BENSTED.

RELATIONSHIP OF ALASTRIM (VARIOLA MINOR) TO SMALL-POX (VARIOLA MAJOR).

SIR,—With all due deference, I would like to suggest to Dr. Killick Millard that, perhaps after all, the above two diseases are one and the same, and that the mild course run by those suffering from alastrim is entirely due to the fact that vaccination has now been extensively practised in Great Britain for over a hundred years. Some little time ago I read an article in *Nature* in which it was stated that immunity is hereditary provided five generations have been immunized, and that this had been clearly demonstrated recently. So when we think of the immunity to malaria found among the native races of Africa and other malaria-infested countries, is it not conceivable that vaccination extending over five generations of our people is beginning to tell in the end, even though some of the people recently infected were never vaccinated? They are benefiting by the vaccination carried out on their parents and grandparents. It would be interesting to see what would happen were alastrim to break out in a mixed population, many of whom had not had ancestral protection.—I am, etc.,

Little Island, County Cork, June 2nd. E. G. FENTON.

PRIMARY VACCINATION OF SCHOOL CHILDREN.

SIR,—It should be widely known among general practitioners that cases of post-vaccinal encephalitis are occurring at the present time in England.

Among the few known points in the etiology of this disease are: (1) it appears to be confined to primary vaccinations of children of school age; (2) it cannot be connected with the use of any particular brand of vaccine lymph. Further, the mortality rate is high. On the other hand, the latest mortality rate of the prevailing epidemic of small-pox is very low, being 0.25 per cent.

There is therefore a heavy responsibility on medical practitioners in deciding at this time whether to proceed with the primary vaccination of children of school age. But there is nothing to suggest that there is any undue risk in proceeding with revaccination, or with the vaccination of infants and adults.—I am, etc.,

London, E.16, June 3rd. PERCY ROSE.

ASSOCIATED CONGENITAL ABNORMALITIES.

SIR,—In the course of Dr. Liesching's interesting memorandum, in your issue of June 1st (p. 993), on strangulation of ovary in an inguinal hernia associated with congenital abnormality of the kidney, he comments on the probability of a congenital abnormality of the one organ being associated with an abnormality of the other, and asks if any similar cases have been reported.

During a recent investigation, not yet published, into the literature of congenital solitary kidney, I have come across details that may be of interest.

Bolaffio (*Zeit. f. Geb. u. Gyn.*, 68, Heft 2, 1911), in an investigation of 99 cases of defects of female genitalia associated with renal anomalies, concluded that female genitalia defects occurred much more frequently in connexion with complete lack of development of the kidney than in association with any other renal anomaly.

Winter (*Arch. klin. Chir.*, vol. lxix, p. 611, 1903), in a collection of 237 cases of solitary kidney, noted an absence of an ovary in four of them.

Campbell (*Annals of Surgery*, July–December, 1928) mentions a case which he encountered in which congenital absence of one kidney was associated with retroperitoneal and atrophic testicle on the involved right side.—I am, etc.,

Glasgow, June 3rd. ALBERT SHARMAN.

THE NEW PYLORUS OPERATION.

SIR,—When Dr. C. D. Mayo was last in England I communicated with him on the subject of the above-mentioned operation; and pointed out that the ordinary posterior no-loop operation for gastric or duodenal ulcer was a perpetuation of a physiological error. Also that after the no-loop operation, done by the ordinary surgeon, the majority of the patients have to be meticulously careful in their diet, and are frequently under the care of a physician; whereas after the new pylorus operation the patients have a normal digestive apparatus and require no dietetic or medical treatment.

As a result of this letter Dr. C. D. Mayo informed his surgical staff at the Mayo Clinic, and one of the Mayo Clinic surgeons, after reading my previous articles in medical journals[1] on the subject of the new pylorus operation, did seventy-five cases in this way. He had two jejunal ulcers in the seventy-five cases—one of whom he said was cured, and the other was receiving treatment at the time of his writing (1926).

A diagram of this operation can be seen in the *British Medical Journal*, April 24th, 1926 (p. 738).—I am, etc.,

G. G. GILLON, F.R.C.S.Ed.

*** The correspondence between the Mayo Clinic and Mr. Gillon can be seen at the Library of the British Medical Association by those interested.

RURAL HYGIENE.

Proposed Memorial to Vivian Poore.

SIR,—The first steps are now being taken to carry out a suggestion of the Council of the National Homecroft Association to raise a homecrofting memorial cottage to that eminent rural sanitarian the late Dr. George Vivian Poore of University College Hospital, London, Milroy Lecturer for 1899, author of *Rural Hygiene* and other works.

A letter from Dr. N. Macfadyen on garden city sanitation appeared in the *British Medical Journal* of December 1st, 1923 (p. 1070), and in your issue of February 9th, 1924 (p. 250), an article was published by Dr. Lionel Picton, medical officer of health for Winsford, Cheshire, on the economic disposal of excreta, on Poore's principles. It is evident that the subject is very much alive in the rural districts, where sanitation is still a serious problem; and the experience of the homecroft movement suggests that a still wider interest is needed on the part of the medical profession.

A committee to assist the Homecroft Association Council in the institution of the experimental cottage memorial is now being formed. The first task is to obtain names and addresses of all old friends and associates of Dr. Poore and readers of his writings who might be interested in the work of the committee or care to join it, together with the names and addresses of any interested in developing homecrofting as a national movement. In order that the committee may be made a large and representative one, names and addresses should be sent to me.—I am, etc.,

J. W. SCOTT,

38, Charles Street, Cardiff, May 31st. Honorary Secretary, National Homecroft Association Ltd.

THE INTERNATIONAL LEAGUE AGAINST RHEUMATISM.

SIR,—Referring to your annotation under this heading on June 1st (p. 1011), may I say that some copies of the second issue of *Acta Rheumatica* are now available in this office for medical men or women who are engaged in the investigation and treatment of rheumatic diseases. The *Acta*, in their present provisional form, may, it is hoped, be of some service to students of these diseases in the countries where they are being especially studied. A copy may still be had on receipt of threepence for postage; also particulars of the next conference of the league, which will be held in Hungary in October, in conjunction with the annual meeting of the International Society of Medical Hydrology.—I am, etc.,

International Society of Medical Hydrology, 139, Marylebone Road, N.W.1, June 2nd. R. FORTESCUE FOX.

[1] *Practitioner*, June, 1920; *Lancet*, January 21st, 1920; Epitome, *New York Med. Journ.*, 1920; *British Medical Journal*, April 22th, and May 29th, 1926.

Medico-Legal.

ALLEGED ILLEGAL OPERATION: CHARGE OF MANSLAUGHTER.

REX v. H. WINDSOR BELL.

At the Central Criminal Court, on May 31st and June 4th, before Mr. Justice McCardie, Dr. Hugh Windsor Bell of Oakley Street, Chelsea, was charged on an indictment of manslaughter arising out of an alleged illegal operation. The defendant pleaded "Not guilty."

Mr. H. D. Roome, for the prosecution, said that in April last a young woman named Kelly went to Dr. Bell regarding her pregnancy, and a few days later, at a house in Kensal Rise, Dr. Bell, the Crown alleged, performed an illegal operation to procure abortion. An accident occurred at the operation, and Dr. Bell afterwards told the girl's sister that he had "made a hopeless mess of it." Distressed at the girl's condition, he had her removed to a nursing home in Welbeck Street, and called in Dr. Richardson, who performed an operation in the attempt to save the girl's life, but without success. It was further alleged that, before the operation attempted by Dr. Bell, he received £75 from the girl, being part of £100 which she had been given by a man friend to cover the expenses.

Evidence as to these allegations was given by the prosecution.

On the second day of the trial Dr. Bell gave evidence. In reply to Sir Henry Curtis-Bennett, his counsel, he said that he qualified in 1914. He had specialized in anaesthetics, and was anaesthetist to several London hospitals. He was also in general practice, and had 1,400 insured persons on his list. The girl Kelly was brought to him by a Mrs. Capper, whom he had known when she was secretary to a colleague of his in a former practice in West London. Kelly wanted to know whether she was pregnant; she had been to another doctor, who thought she was not. She told him that her periods had stopped since November, and it was then April. She also told him that she had taken drugs, and had syringed herself with hot soap and water. He found signs of pregnancy, but on making a bimanual examination the size of the uterus did not appear to him as large as he would have expected, judging from the time for which the menstrual periods had ceased, and he discovered also the fact of some blood-stained discharge. He came to the conclusion that the membranes must have ruptured, and that a miscarriage had started. He told her that she ought to go into a nursing home, but she was horrified at the idea because she was an unmarried woman and her family would learn of her condition. It was therefore arranged that Mrs. Capper should take her into her house.

The judge asked questions with regard to the syringe the girl had used. He pointed out to the jury that the effect of drugs was to stimulate movement, and possibly to cause expulsion of the foetus; in addition, a syringe at the mouth of the uterus might cause irritation, and that by itself might cause the muscles to move.

Continuing, the defendant said that he told the girl that with commencing miscarriage she might have to be up for a fortnight or more. She gave him the name of someone who, she said, was a very wealthy man, and who had given her £100, and she offered him (Dr. Bell) £75 as an inclusive fee. During the next day or two he became rather worried about her condition. There was pain and blood-stained discharge, and on April 8th—the girl had first seen him on April 4th—hearing by telephone that she was in a very distressed state, he went to see her, and after examination came to the conclusion that he ought to remove the foetus. He gave her chloroform, and first put in a speculum, and after grasping the neck of the womb with the forceps, he inserted in turn about six dilators of increasing size. Unfortunately, one of the dilators made a puncture in the anterior wall of the uterus; the uterus was in malposition, or such a puncture would not have been possible. Unaware that the puncture had taken place, he put in the forceps for extracting the uterine contents. He brought down a limb of the foetus, and then, inserting the forceps again, they slipped from whatever they held, and, trying a second time, he brought down something which he realized was a portion of intestine. He immediately telephoned Dr. Richardson, and got the girl into a nursing home.

In cross-examination by Mr. Roome, Dr. Bell agreed that his contention was that Miss Kelly actually performed an illegal operation on herself with a syringe and hot soapy water. He explained that he had not told the full story at the inquest or the police court proceedings because he had been advised by his solicitor to reserve his defence. He would not say that the £75 fee was enormous. He expected to attend the girl for a fortnight or longer. Asked why, if there was nothing to hide, he did not ask a colleague to give the anaesthetic, he said that being an anaesthetist himself he did not look upon the giving of an anaesthetic quite as an ordinary doctor would. He usually gave a little chloroform at the end of a maternity case, and did not call in anyone else.

Mr. Aleck W. Bourne, gynaecologist, practising in Harley Street, said that the combination of drugs with local interference as by syringing might, and did occasionally, induce abortion. If the doctor was satisfied that a miscarriage was inevitable it was a common practice to expedite it should there be undue delay or other complications. The medical man must decide on the circumstances before him. The procedure depended on the case, but he could quite imagine speculum and dilators being necessary. It was difficult to understand how a wound could be made in the front of the uterus if it was in normal position, but if it was turned backwards a puncture in that part of the wall would be likely to occur in the hands of a man unaccustomed to deal with such emergencies. If such a puncture were made it was common for the uterus to contract and push the foetus out through the hole thus made, enlarging the hole to a very great extent. He agreed that in a pregnancy of eighteen weeks it would be difficult for drugs alone to induce miscarriage, but if syringing were used and the syringe nozzle caused any injury at or about the mouth of the womb miscarriage might occur.

Mr. Justice McCardie's questions to this witness led Mr. Roome to remark, "Your lordship is more expert than the experts."

The Summing-up.

His lordship said that Mr. Roome had remarked that the defendant, who admittedly bore a very good character, was fortunate in escaping a charge of murder. The judge was glad that no such charge had been brought. The essence of murder was intent to kill, and he was glad that no attempt had been made to present against this defendant any charge based on the harsh, mediaeval, and repulsive doctrine of constructive murder. The charge was manslaughter; it was not negligence, and therefore in substance the question was whether he performed an illegal operation. It was vital to notice that word "illegal." Certain operations were legal and necessary in the last stages of pregnancy to save the life of the mother, and if possible the life of the child, but there was a stage before that when an operation to bring away the foetus might be legal, and not only legal but imperative from the medical point of view. If once the sac which contained the foetus were broken, and the liquid escaped, blood poisoning might ensue should the foetus not be removed. According to the defence it was this necessary operation which Dr. Bell performed.

There were different methods of procuring abortion. The reluctance of doctors to state those methods might be right; no one would desire to spread the knowledge of abortive methods, but in a court of justice it was essential that every item of experience should be laid before the jury. A very simple process might lead to the commencement of a miscarriage; for example, the syringe itself might set up a local irritation which induced movements of the uterus. One factor in this case ought not to be overlooked—namely, the anxiety of the girl herself, finding that she, without the sanction of marriage, was pregnant.

As to what happened at the operation there was no direct evidence except that of the defendant himself. The Crown had made a point of the secrecy with which the operation was conducted. The girl went to a private house; he agreed it would have been better if she had gone into a nursing home. On the other hand, in a nursing home she would have had to give certain particulars about herself; and whether she contemplated undergoing an illegal operation or whether a miscarriage had commenced, she would still desire to have secrecy. It was asked why Dr. Bell did not call for the help of an anaesthetist. But it should be remembered that he had himself a singularly high record as an anaesthetist; moreover, the girl might not wish more than one doctor to be acquainted with her misfortune. Medical men had certain obligations with regard to secrecy, and had insisted again and again that their efficacy as medical men in many aspects of their practice depended upon the confidence of their patients that secrets would not be divulged. Again, there was the fact of the £75. It was a really substantial sum. It had been suggested that the services of a first-rate obstetric surgeon might have been obtained for that sum. But, of course, it was an inclusive fee for services which might have extended over a fortnight or more. Mr. Roome had also made a point of the fact that the defendant had made no record of this case in his books. To this there were two answers: that he was arrested at an early stage, and, again, that the question of confidence arose; if the £75 had been entered in his books it would have been seen by anyone who audited them.

The words used by Dr. Bell after the operation were equally consistent with the commission of a surgical blunder or with a crime. There were certain points to be considered in his favour. As soon as this unfortunate piercing of the wall of the uterus was discovered, he might have said, "Let her stay here" (in Mrs. Capper's house), and have tried to hush up the affair, but instead he immediately arranged for her to go to a nursing home and for Dr. Richardson to perform an operation. He said at once that he was responsible. If he had performed an illegal operation as distinct from committing a surgical blunder, would he have been so frank in stating his responsibility for it? A very important witness was Mrs. Capper. She was a witness for the prosecution

not for the defence, and some of her evidence was not favourable to the defendant, but if she was telling the truth the case for the defendant was enormously strengthened. Mrs. Capper had stated that the girl had asked her for a towel or cloth because she had a discharge; also that before Dr. Bell arrived and performed the operation the girl was in such great agony that she begged her (Mrs. Capper) not to leave her. This pain was indicative of commencing miscarriage. Finally, the judge reminded the jury that the burden rested upon the prosecution of producing satisfactory proof of Dr. Bell's criminal intention, and if in doubt upon the matter the jury were entitled—nay, bound—to remember that up to the present Dr. Bell had enjoyed the highest possible reputation.

The Jury Disagree.

After more than an hour's retirement the jury failed to agree. The case was postponed to next sessions, Dr. Bell being released upon his own recognizances.

ALLEGED RECEPTION OF LUNATICS IN AN UNLICENSED HOUSE.

ON May 30th, at the South-Western Police Court, the magistrate, Mr. Kenneth Marshall, following a conflict of medical testimony, dismissed summonses against two persons accused of receiving five lunatics into a nursing home at North Side, Clapham Common, not licensed for the purpose under the Lunacy Acts.

At a previous hearing Mr. Gerald Dodson, on behalf of the Director of Public Prosecutions, had stated that the nursing home carried on by the defendants, was a perfectly respectable and reasonably conducted house, but produced medical evidence to the effect that five female inmates were certifiable lunatics. One of the medical witnesses called by the prosecution admitted that these patients were not dangerous to themselves or others, though he would except one in whom there were suicidal tendencies. The patients' own medical attendants stated that they were not, in their judgement, certifiable, and there was no reason why they should be put under restraint. One of the defendants stated that she had conducted the home for fourteen years, and her patients, principally elderly people, were all attended by their private doctors. She made a practice of sending any patient of whose condition she felt suspicious to St. John's Hospital for observation, and added that the Lord Chancellor's Visitor for Lunacy had certified none of the patients as lunatics.

The magistrate, in dismissing the summonses, said that he could not but express surprise that it had been found necessary to take proceedings against the defendants; even an expert in mental disorder called on behalf of the prosecution had hesitated in asserting that the patients were certifiable. The medical attendants of the patients themselves, though not experts, were, in his view, qualified to give an opinion; they saw the patients frequently, whereas the specialist had seen them only once. In face of the evidence he would be doing wrong to say that the five persons were lunatics.

The Services.

INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 19th, at 7.15 p.m. Lieut.-Colonel D. G. Crawford, "the historian of the service," has been invited to take the chair. Tickets, and all particulars, may be obtained from the joint honorary secretary, Major Sir Thomas Carey Evans, *M.C.*, 31, Wimpole Street.

DEATHS IN THE SERVICES.

MAJOR-GENERAL CHARLES EDWARD POLLOCK, C.B., C.B.E., D.S.O., Army Medical Service (ret.), died at Northwood, Middlesex, on May 18th, aged 61. He was born on April 16th, 1868, at Paisley, the son of Mr. Alexander Pollock of Greenhill, Paisley, and was educated at Wellington College and at Guy's Hospital, and took the M.R.C.S. and L.R.C.P.Lond. in 1891. He entered the army as surgeon lieutenant on January 30th, 1893, attained the rank of colonel on December 26th, 1917, became major-general on June 1st, 1922, and retired on June 1st, 1926. He served in the Tirah campaign on the North-West Frontier of India in 1897-98 (medal with two clasps); in the South African war in 1902, in operations in the Orange River Colony and Cape Colony (Queen's medal with two clasps); and in the war of 1914-18, as A.D.M.S. of the 15th Division, and as D.D.M.S. of the 4th and 6th Corps (mentioned in dispatches, in the *London Gazette* of January 4th, May 29th, and December 24th, 1917). He was awarded the D.S.O. in 1917, the C.B.E. in 1919, and the C.B. in 1921. He was the author of a report on venereal diseases and scabies in the army, submitted to the Advisory Board for Medical Services in 1904. He married Winifred, daughter of Mr. C. E. H. Jay of Felixstowe, and leaves a son and two daughters.

Obituary.

ROBERT WELSH BRANTHWAITE, C.B., M.D.,

Director of Medical Services, Stoke Park Colony; formerly Medical Commissioner, Board of Control.

THE announcement early this week of the death of Dr. R. W. Branthwaite, director of medical services at the important colony for the care and treatment of mental defectives at Stoke Park, Bristol, will have occasioned a sudden sense of loss to many, and even to the few who knew that, with the cheerful courage which ever distinguished him, he was carrying on his good work almost up to the day of his death, notwithstanding symptoms which had occasioned anxiety to others.

The son of Harrison Branthwaite, F.R.C.S., of Harlesden, Robert Welsh Branthwaite was born on May 27th, 1859, and thus died a few days after he had completed his seventieth year. Educated at Heighington Grammar School, at Charing Cross Hospital Medical School, and at Brussels University, of which he was a Doctor of Medicine, he took the diploma of M.R.C.S. in 1881 and the L.R.C.P. in 1884. His interest in mental diseases was manifested early in his professional career, and in 1882 he was appointed an assistant medical officer to the Chester County Mental Hospital at Parkside. After two years' work there he was appointed, at the early age of 24, to the medical superintendentship of Dalrymple House, Rickmansworth, where for fifteen years he ably administered that institution and two similar establishments under the Habitual Drunkards Act.

Photo by Army and Navy C.S.S., London.

In 1899, in recognition of his grasp of the subject and his marked ability, Dr. Branthwaite was appointed by the then Home Secretary, Sir Matthew White Ridley, to the Home Office staff as inspector under the Inebriates Act, and was engaged in the organization and establishment of reformatories for the care and treatment of criminal and recidivist drunkards under the Inebriates Act. To enable him to assist in the management of State reformatories he was appointed an inspector of prisons, and for four years acted as medical adviser to the Reformatory and Industrial Schools Department. His work under the Home Office continued until the beginning of 1914, and during this period of a life of incessant activity he made many valuable contributions to the subject of which he was a master, and attended as an official delegate several international congresses, including the International Home Relief Congress in Edinburgh (1904), the International Congress of Alcoholism at Stockholm (1909), London (1910), and The Hague (1911). He was also an active member of the Departmental Committee on the Inebriates Act (1909).

In February, 1914, Dr. Branthwaite joined the Board of Control for England and Wales as an inspector, and in November, 1916, was appointed a Commissioner of the Board, in which capacity he remained until he retired under the age limit in the autumn of 1926. During his years of office in the Board of Control, interrupted by two years of military service, he interested himself especially in two matters—namely, infectious diseases in mental hospitals and the dietaries of the patients in public mental hospitals—and it is not too much to say that his investigations and the work of the departmental committees over which he presided have been largely instrumental in bringing about the improved conditions which obtain

to-day. He was an active member also of the Departmental Committee on Morphine and Heroin Addiction. Unsparing of himself, whatever he did he did with all his might. On leaving the Board of Control, and desirous, even at the cost of a well-earned leisure, to place his special knowledge and experience at the service of the community, he accepted the medical directorship of the colony for mental defectives at Stoke Park. Here his loss will be severely felt by patients and staff alike; and, though only for a brief time we hope, his plans for the employment of the colony as a place for special study and research in mental deficiency, in association with the University of Bristol Medical School, have been interrupted.

Dr. Brauthwaite leaves a widow and one daughter, to whom we tender our sympathy. Many will mourn his loss, for he had friends all over England and Wales. Courage and sincerity, say his friends and colleagues of the Board of Control, were the dominating characters of his life and work. In early and middle life he met and overcame difficulties which would have daunted most men. When the war came, although well on in the fifties, he went to France as regimental surgeon, was present at three engagements, was mentioned in dispatches, was wounded, and finally incapacitated for further overseas service. In private life his relations with all with whom he came in contact were marked by unusually clear insight and consequent sympathy. He was a great and true friend, and there are many to whom his death will mean a blank that cannot be filled. His friends will remember him as one who had "courage and gaiety and a quiet mind."

DR. HUGH SMITH MORRISON died on May 21st, at his residence at Blackhill, Coleraine, and deep regret will be felt, both by the profession and by the general public, in Ulster. He had not been in good health for some years, and had gradually retired from his large practice and numerous public offices which his activity and ability had really forced upon him. Hugh Morrison was born in 1853, and graduated M.D. from the old Royal University of Ireland in 1884, obtaining also in the same year the diplomas L.R.C.S. and L.M.R.C.P.I. He began his professional life in County Londonderry, where he made for himself a name and gained the trust and affection of his patients in a very large private practice. Nothing could withstand his energy, and he was placed by the profession and the public in numerous positions of responsibility and honour. Among other posts he was chairman of the South Londonderry Unionist Association, and of the County Londonderry Branch of the Irish Unionist Alliance. He was nominated by the medical association of the county as candidate for Queen's University of Belfast in the Northern Parliament of Ireland in 1925; the selection was unanimously adopted, and he sat in the Northern Parliament for many years. Possessing a good voice and many of the qualifications of a keen debater, he was no silent member, but made many valuable contributions to debates on social matters and education. His caustic criticism and unfailing good humour were appreciated on all sides and by all parties; he never omitted to lend a hand in the solution of agricultural problems, wherein he had practical knowledge. As secretary of the medical societies in County Derry, and as a member of the North-East Division of the Ulster Branch of the British Medical Association, he gave wholehearted support to medical reform. Dr. Morrison was a keen Presbyterian, and often spoke in the meetings of the General Assembly. As coroner for the Coleraine division of Derry he discharged his duties with great care, ability, and tact. He was the author of *Modern Ulster: its Industries, Customs, and Politics*. Few have lived such an active, full life; still fewer have left such an empty space, and one so hard to fill.

DR. ROBERT WISE, who died on May 17th, aged 63, received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1888, and proceeded M.D. four years later. His life was spent in general practice. He took particular interest in obstetrics, being a member of the Obstetrical Section of the Royal Society of Medicine, and in former years a Fellow of the Obstetrical Society of London. He designed a special type of uterine forceps for use in cases of soft cervix, and published articles on practical obstetrics. During the war he was employed by the War Office for medical examination of recruits, and subsequently for pension assessments. Dr. Wise was a member of the British Medical Association. He leaves a widow, one son, and two sisters.

THE LATE MR. ARTHUR CHEATLE.

MR. H. NORMAN BARNETT writes: As one who was brought into close touch with Arthur Cheatle during the preparation for and the holding of the 1925 Annual Meeting at Bath, and on many subsequent occasions, I would like to bear record to the memory of this truly great man who has passed from us while still in his prime. His wonderful brain power and capacity for investigation are, of course, widely known. To these was added an unfailing courtesy and very real kindness of heart, which I personally experienced on many occasions. The truth in scientific research was a passion with Cheatle. His simple and rather shy manner was the badge of his true greatness. His loss to his colleagues in otology will be hard to replace, and his memory will be enshrined in many hearts, but I would be glad to see something tangible done to perpetuate it.

Universities and Colleges.

UNIVERSITY OF LONDON.

DR. H. W. C. VINES has been recognized as a teacher of the University in pathology at Charing Cross Hospital Medical School.

The regulations for the M.B., B.S. Examination are to be amended by the substitution for paragraph (b) (i) on page 243 of the Red Book, 1928–29, and page 230 of the Blue Book, September, 1928, of the following:

> (i) An examination of a patient, and a written report thereon, three-quarters of an hour being allowed for the former and one hour for the latter.

The matter to be reconsidered after one year.

The regulations for the M.D. Examination, Branch IV, have been amended by the substitution for the words "*n. clinical* examination" (Red Book, 1928-29, p. 247, and Blue Book, September, 1928, p. 234) of the following:

> A practical and clinical examination, including reports (either written or verbal, or both) on clinical cases, pathological and other specimens, and other material suitable for an examination of a practical character.

Regulation 3 of the examination for the Diploma in Psychological Medicine has been amended to read as follows:

> The examination for the diploma is open to any candidate whose name is in the *Medical Register*, provided that, before being admitted to Part B, the candidate shall either (a) have held for not less than six months a resident or whole-time appointment at an institution [illegible] for mental diseases recognized for the purpose; less than twelve months the practice of ions), or such other practice as may from the University.

Dr. A. M. H. Gray and Professor William Wright have been appointed members of the new Senate under Statute 43 (iii) (c), as representatives of the deans or chief executive officers of the general medical schools.

Applications for the William Julius Mickle Fellowship must reach the Principal of the University not later than the first post on October 1st. It is of the value of at least £200, and is awarded annually to the man or woman who, being resident in London and a graduate of the University, has, in the opinion of the Senate, done most to advance medical art or science within the preceding five years.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

The examination for the two Goldsmid Exhibitions, entitling the holders to the final course, will be held on July 19th and 20th. They are open to students preparing for the degrees of the Universities of London, Oxford, Cambridge, Durham, or other British universities, or for the diplomas of the Royal Colleges of Physicians and Surgeons, or for the licence of the Society of Apothecaries. Notice to compete must be received by the secretary at the office of the Medical School on or before July 6th.

The examination for the Buckmill Entrance Scholarship will be held on June 25th. The holder is entitled to the course of intermediate medical studies (including Part II of the Preliminary Scientific) at the University of London, University College, and the final course at University College Hospital and Medical School.

Further particulars can be obtained on application to the Secretary, University College Hospital Medical School, Gower Street, W.C.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—W. T. Ellis, A. Freitag, J. D. B. Games, W. St. A. Hendricks, L. G. E. K. Lewis, B. J. Niall.

MEDICINE.—F. W. Crossley-Holland, A. Freitag, K. E. Gallaher, K. M. Seedat.

FORENSIC MEDICINE.—P. S. Balachandran, A. Freitag, K. E. Gallaher.

MIDWIFERY.—A. Campbell, B. H. El Sawy, B. L. Fishout, A. Freitag, C. Parthasarthe, A. Scher.

The diploma of the Society has been granted to Messrs. F. W. Crossley-Holl[illegible] Freitag, and K. E. Gallaher.

Medical News.

THE summer dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 14th, at 7.45 for 8 p.m., with Mr. F. F. Muecke in the chair. Mr. W. Sampson Handley and Professor F. R. Fraser will be the official guests of the Association. All medical visitors from Australia and New Zealand, whether members of the Association or not, are invited to be present. The cost of the dinner is 10s. 6d., payable at the table. Communications should be addressed to Mr. P. J. Jory, 26, Queen Anne Street, W.1.

THE annual dinner of the Cambridge Graduates' Medical Club will be held at Jesus College on Friday, June 28th, at 7 p.m., with Sir Humphry Rolleston, Bt., President of the Club, in the chair. The honorary secretaries are Mr. Reginald Vick and Dr. F. G. Chandler.

THE annual dinner of the Harveian Society of London will be held on Thursday, June 13th, at 7.30 for 8 o'clock, in the Connaught Rooms, Great Queen Street, W.C.

A SYMPOSIUM on some diseases of Jews is being opened by Sir Humphry Rolleston on Thursday, June 13th, at 3 p.m., at the London Jewish Hospital, Stepney Green, E.1. The following will take part in the discussion: Drs. J. Burnford, W. M. Feldman, and J. Brander, and Messrs. A. H. Levy, M. Sourasky, and A. Sourasky.

AT a special meeting of the Odontological Section of the Royal Society of Medicine on Wednesday, July 17th, at 5.30 p.m., a bust of the late John Howard Mummery will be unveiled, and will be presented to Dr. A. D. Black, professor of special pathology and operative dentistry in the North-Western University, Illinois. Professor Black will receive the bust on behalf of the North-Western University as a gift from its London alumni.

THE provincial meeting of the Section of Disease in Children of the Royal Society of Medicine will be held at Nottingham on Saturday, June 22nd.

A SESSIONAL meeting of the Royal Sanitary Institute will be held on Friday, June 21st, in the Festival Hall, at the North-East Coast Exhibition, Newcastle-upon-Tyne, when discussions will take place on the problem of feeding the premature infant, the need for a maternity service, the importance of ante-natal supervision, eliminating the tuberculous cow, hygienic milk supplies, and clean milk in the Northern counties. The chair will be taken at 2.30 p.m. by Dr. Charles Porter. In the evening a public lecture on smoke pollution will be given at 8 o'clock by Professor Leonard Hill, F.R.S., and followed by an open discussion.

AT a meeting of the Optical Society to be held at the Imperial College of Science and Technology, South Kensington, on Thursday, June 13th, from 5.30 to 10 p.m., experiments, demonstrations, and exhibits will be on view, arranged by the Technical Optics Department of the Imperial College.

THE general board of the National Physical Laboratory, Teddington, will hold its afternoon reception this year on Tuesday, June 18th, when visitors will be received by the chairman, Sir Ernest Rutherford, O.M., President of the Royal Society, at 3 o'clock.

A CLINICAL meeting will be held at the East London Hospital for Children, Shadwell, E., on Wednesday next, June 12th, at 4.15 p.m., when a discussion on neurological diagnosis in children will be followed by a demonstration of cases of interest in the wards. Tea will be served at 4 p.m.; all practitioners are cordially invited.

A PUBLIC lecture on some aspects of protoplasmic membrane will be given in the department of anatomy and embryology of University College, Gower Street, W.C.1, by Professor Robert Chambers of the department of biology, Washington Square College, New York, on Monday next, June 10th, at 5 p.m. The chair will be taken by Professor J. P. Hill, F.R.S. The lecture is open without fee to students and others interested in the subject.

THE following lectures in the series for the M.R.C.P. course arranged by the Fellowship of Medicine will be given at the Medical Society, 11, Chandos Street, Cavendish Square, at 8.30 p.m.: Tuesday, June 11th, Dr. Bernard Myers, on the differential diagnosis of splenomegaly, with the treatment of the diseases concerned; Friday, June 14th, Dr. L. S. T. Burrell, on bronchiectasis, abscess of lung, and empyema. A lecture will be delivered at the Queen Mary's Hospital, Stratford, E.15, on June 12th, at 2.30 p.m., by Dr. A. A. Osman, on debility in children and adults. An aural clinical demonstration will be given at the Royal Ear Hospital, Huntley Street, W.C.1, on June 13th, at 2 p.m., by Mr. E. A. Peters. A course in ophthalmology is in progress at the Royal Westminster Ophthalmic Hospital, Broad Street, Holborn; it includes lectures and clinical work every afternoon. At the Chelsea Hospital for Women, Arthur Street, there will be a course in gynaecology from June 10th to 22nd, and a special whole-day course in diseases of the chest will be held at the City of London Hospital for Diseases of the Heart and Lungs from June 10th to 22nd. Three courses will begin on June 24th—namely, one in general medicine and surgery lasting a fortnight at the Prince of Wales's Hospital, Tottenham, and another of the same duration in diseases of children at the Children's Clinic and associated hospitals. The third course, which is in proctology and lasts for one week, will be held at St. Mark's Hospital, City Road. Copies of syllabuses for all courses, the complete list of special courses for 1929, and information on general post-graduate work is obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Medical Research Council has issued a report (No. 132) on the early treatment of syphilis, embodying a survey of records from St. Thomas's Hospital by Colonel L. W. Harrison. Two points of special interest in it are: a reference to the diversity of individual responsiveness to treatment; and the apparent increase in liability to subsequent neuro-syphilis when arsenobenzene compounds are used in the earlier weeks of treatment without mercury or bismuth. Detailed reference will be made to this report in our next issue.

THE Council of Epsom College will shortly award a Sir Walter Buchanan Scholarship, the value of which is about £38 a year. The rule fixed by the founders of the scholarship is as follows: The Sir Walter Buchanan Scholarship is primarily intended for the sons of deceased or prematurely invalided officers of the Indian Medical Service, or, failing any such candidates, for the sons of legally qualified medical men of pure British parentage in necessitous circumstances who have practised medicine for at least five years in India. Forms of application can be obtained from the Secretary, Mr. J. B. Lamb, 49, Bedford Square, W.C.1.

THE nineteenth French congress of legal medicine will be held in Paris from June 24th to 26th under the presidency of Professor Sorel, when the following subjects will be discussed: sudden death, introduced by MM. Hoger-Gilbert of Brussels and Laignel-Lavastine of Paris; cruelty to children, introduced by MM. Parisot and Caussade of Nancy; the pre-nuptial certificate, introduced by MM. Vervaeck of Brussels and Leclercq of Lille; and the responsibility of epileptics, introduced by M. Collier of Paris. Further information can be obtained from M. Piédelièvre, 24, Rue Gay-Lussac, Paris.

THE International Labour Office has published nine leaflets, Nos. 141 to 149, dealing with calcium and calcium carbide; synthetic camphor; canning and food-preserving industries; cantharides and carbanilide; cements; chlorates and alkaline chlorites; chloroform, chlorpicrine, chromium and chromates; cocaine, cochineal, codeine, colcothar, and colocynthine; and copper boiler-making. They may be obtained from the director of the London office of this organization, 12, Victoria Street, S.W.1.

A NEW quarterly periodical has appeared under the title of *Archives de l'Institut Prophylactique*. The editor, Dr. Arthur Vernes of Paris, contributes to the first number—January to March, 1929—a review of the campaign against syphilis. There is also a joint paper by him and Drs. R. Brico and A. Gager on some experimental work in relation to the serological diagnosis of cancer. The periodical is published by Masson et Cie; the price for countries outside France is 40 fr. for the year.

THE recently published fourth volume of transactions of the Kaiser Leopold Academy at Halle contains papers by twenty-three members from North, Central, and South America, and is dedicated to Professor William Welch of Johns Hopkins University.

MR. ISIDORE D. MORRISON of New York has made a gift of £20,000 and a promise of £2,000 a year for the establishment of an ophthalmic institute at the Hebrew University in Jerusalem.

DR. R. W. MacKenna and Dr. G. C. Mort have been appointed to the Commission of the Peace for the City of Liverpool.

DR. C. H. DURRANT, chief medical officer of the St. Kitts-Nevis Medical Service, has been appointed an official member of the Legislative Council of the Presidency of Saint Christopher and Nevis.

DR. ABRAHAM FLEXNER, director of the Department of Educational Studies of the International Education Board in New York has been elected a doctor *honoris causa* of the Medical Faculty of Berlin.

PROFESSOR ROUSSY and Dr. Lesné have been elected members of the Académie de Médecine.

TESTIMONIAL TO SIR RONALD ROSS.

CONTRIBUTORS TO THE APPEAL FUND.

IN the *British Medical Journal* of May 11th (p. 879) we published a letter from Sir James Barr and others informing our readers that a fund, called the Ross Award Fund, was being started in order to give some recognition to Sir Ronald Ross for his discoveries on the mode by which malaria is carried, and for his lifelong efforts regarding the prevention of that disease. The letter stated that donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15, cheques to be crossed "Ross Award Fund a/c." The fund was opened with a sum of £344 13s. 6d., subscribed spontaneously by American friends and some personal friends of Sir Ronald Ross in England. The names of these subscribers are printed below, together with a list of donors whose contributions were received up to May 17th. On that date the total amount received was £2,490. The list published below does not include anonymous contributors or contributors whose initials only have been supplied.

Original Contributors.

American Friends per Dr. T. D. *Acland*, Sir James Barr, Sir Henry Cowan, Mrs. B. M. Guille, Col. W. G. King, Viscount Leverhulme, Per the *Daily Mail*, Brisbane.

Contributors May 15th to May 17th.

Mrs. R. Marshall Allen, T. Atkinson, N. M. Allen, C. C. *Atchinson*, Mrs. E. L. *Adams*, H. M. Atkinson, Miss E. K. Adderley, Mrs. S. Arter, Miss Andrew, Commander R. Allison, J. A. Arnold, Miss P. *Andrews*, Mrs. E. G. Appleby, Mrs. R. W. Adamson, B. C. Annersley, J. M. A. Annersley, Miss E. Augener.

Mrs. Burke, Miss S. Besley, Mr. F. M. Bathurst, Lady Barrington, Dr. A. Balfour, Miss L. J. Barlow, A. A. Bell, Miss Bellairs, Miss B. Barlow, Miss K. Barlow, Mr. J. Byers, Miss I. Bellairs, Miss A. C. Bryson, Mr. and Mrs. F. T. Bellward, Capt. Barnard, Mr. J. Barker, Mrs. S. J. Bedford, Miss M. Bearman, Miss C. Barwell, Mr. T. Bickerton, Mr. R. E. Bucknell, Mr. and Mrs. *Allerne Brown*, Miss E. A. Barron, Miss S. Barclay, Mr. W. H. *Brady*, Mr. J. E. Boustead, Miss K. L. Buchan, Lady Grace Barry, Mrs. V. H. Brock, Dr. D. Booth, Mrs. H. Bull, Mr. A. C. Butler, Mrs. M. Bell, Mr. E. Burtt, Mr. C. C. Browne, Mr. H. Brinton, Professor H. *Briggs*, Mrs. *Bell*, Mr. A. J. Boult, Col. L. J. Blanford, Rev. G. H. Barrett, Mr. F. H. Browne, Mr. G. W. *Beams*, Miss N. L. Banyard, Mr. M. K. Burton, Mrs. Blanford.

QUERIES AND ANSWERS.

PRODUCTION OF IMMUNITY TO TUBERCULOSIS.

DR. GRIFFITH EVANS (Carnarvon) writes to ask whether the tuberculin recommended by Dr. Nathan Raw (*British Medical Journal*, May 25th, p. 950) is available for general use, and, if so, where it can be obtained.

*** We referred this inquiry to Dr. Nathan Raw, who informs us that the vaccine is prepared and standardized by Messrs. Allen and Hanburys, Vere Street, W.1, from cultures supplied from Dr. Raw's laboratory in the University of London.

INTRACTABLE DIARRHOEA IN A DIABETIC PATIENT.

DR. E. MCPHERSON (Glasgow) writes: "R. M.'s" patient (June 1st p. 1023), in all probability, is suffering from hypochlorhydria, with over-rapid emptying of the stomach, a condition which, by means of gastric analyses, I have found to be present in a large proportion of diabetic patients. Many such cases show marked improvement on the administration of dilute hydrochloric acid; 45 minims or more may be taken in a glass of water with each meal. The fluid, which most diabetic patients learn to enjoy as a refreshing drink, should be sipped slowly during and after the meal. The treatment may be continued for prolonged periods, with or without insulin administration.

DURATION OF LIVER TREATMENT OF PERNICIOUS ANAEMIA.

DR. F. L. RIGBY (Preston) writes: In reply to "W. L." (June 1st, p. 1023), who asks for advice regarding treatment of pernicious anaemia, I may say that, as a sufferer two years ago, when the useful effect of liver was not known, I went into a hospital for transfusion, which was given to me. During my stay there the new treatment became known, and at first a strict liver diet was prescribed, but, as time went on, I found that smaller quantities would suffice, and I am now able to keep a perfectly healthy blood picture by taking about 2 oz. of fried liver with bacon three times a week. While on the strict diet I found the monotony adequately relieved by all kinds of vegetables, sauces, mushrooms, etc., served with the liver. I believe that it is wise to press forward with the ingestion of liver for the sake of its further effects. The nervous troubles (paraesthesia) are, I am sure, gradually relieved by it. I have taken very little "extract," using almost always the actual liver itself, cooked or raw (minced), and served in various ways.

INCOME TAX.

Cessation of Practice: Cash Basis.

"A. B." relinquished his practice last July. His liability up to that date was settled on the cash receipts basis, but he has, of course, subsequently received payment of fees for work done prior to retirement.

*** He is not liable to account for income tax on the fees so received. Income tax is assessable on earnings, whether actually received or not, and his past payments of tax—calculated for convenience on the basis of cash receipts as being over a period of years equivalent to the value of the annual bookings—have covered the whole of his liability. Incidentally his successor will, no doubt, be denied the convenience of the cash basis for his first two or three years—that is, until his annual cash receipts have caught up to the value of his bookings.

Change in Partnership: Cash Basis.

"NOMONE" acquired a share in a partnership as from January 1st, 1928, and inquires as to the method of dealing with his liability.

*** He will have to account for tax on the full amount of his earnings, whether received by him in cash or not, and will not obtain the benefit arising from the operation of that principle until he leaves the practice and then has cash receipts on which he will then already have accounted for income tax.

Depreciation of X-Ray Apparatus.

"RADIO" has been allowed depreciation in respect of his *x*-ray apparatus since 1926, but only at the rate of 5 per cent. Should he have received a larger allowance, and, if so, can he claim for past years?

*** We consider that 10 per cent. at least should be allowed. On a written-down basis it would take twelve years to reduce the value from 100 per cent. to 24 per cent. at that annual rate. "Radio" cannot claim in respect of past years, but should be careful to make a claim for obsolescence if and when he replaces the apparatus, because he will then obtain a larger allowance than he would have done if the higher rate of depreciation had been applied.

Depreciation of Car: Balance Sheet.

"A. E. B." has been advised by his accountant that the depreciation allowance will be given "only where a balance sheet is prepared for the inspector of taxes."

*** We understand that this requirement is usual in the case of manufacturing or trading concerns, but it is not applied to professional profits (the result of personal earnings), and we do not think that the inspector in question is at all likely to require a balance sheet.

Renewal of Car: Improvement.

"W. A. T." bought an F car in 1920 for £404, and sold it in 1928 for £10, when he bought a car of superior grade for £321. He has claimed as an expense £321−£10=£311 (less a deduction in respect of private use), but the inspector of taxes claims to make a further deduction of £80.

*** The £80 presumably is intended to represent that portion of the outlay which went in improving rather than replacing the car equipment. "W. A. T." is entitled as an expense to the amount which would have been incurred in replacing the old car with one of similar grade; anything over that amount is capital expenditure. This may seem harsh, but it arises from the fact that the present price level for cars is below that of 1920, and the converse was the case as regards replacements effected during the high-price period.

Motor Car Transactions.

"R. M. L." has bought two new cars, one at £275 and one at £152, selling for £50 his former car, bought in 1922 for £625. He has throughout been allowed depreciation in respect of this car. What claim should he make?

*** (1) Obsolescence allowance—that is, £625−£425−£152=£48. The £425 is apparently the total amount of depreciation allowance received by "R. M. L." for the financial years 1923-24 to 1929-30 inclusive. (2) Depreciation allowance for 1930-31 on the new cars—that is, £275+£152=£427 at 15 per cent.=£64.

N.B.—"R. M. L." does not state the date to which his professional account is prepared for income tax purposes; we have assumed that the car transaction took place after the closing date of his account for 1928—for example, after March 31st, 1929, if the account is usually prepared to the end of that month.

LETTERS, NOTES, ETC.

POISONING FROM EXHAUST FUMES.

"M.R.C.S." writes: Referring to the note of "M.D., B.S." in the *Journal* of April 20th (p. 752), describing a case of exhaust gas poisoning, it would appear that still another clinical entity will have to be added to the already complicated list of "compensation" disorders. I had a similar case a few weeks ago. The patient was a driver of a motor lorry doing long distances—namely, regular and frequent runs in the road goods service between Newcastle-on-Tyne and London. The story was that there had been complaints to the owners of the lorry with reference to a defective exhaust pipe leaking under the driver's cab. The pipe was not repaired, and on a journey to London the driver had found himself one night, returning from unconsciousness, in a ditch by the wayside. He had apparently been "gassed" to the extent of losing control of his lorry. He was attended to in a local hospital, and returned North in a few days with the same lorry. On reaching Newcastle-on-Tyne he was ill and half collapsed, and obliged to go sick. The outstanding feature of his illness was an acute hyperemesis of three days' duration. He was incapacitated for no less than six weeks, a fact which caused great trouble on account of compensation claims. Employers are naturally reluctant to ask the companies with which they have their men insured under the Compensation Acts to pay compensation money in cases which appear on the surface ordinary national health insurance cases. If these cases of "exhaust gas poisoning of motor drivers" become more frequent, it will be necessary to decide whether they should be dealt with under the provisions of the National Health Insurance Acts or under the Workmen's Compensation Acts. Of similar significance is the stomach trouble found in some of the coal-fields among the miners who use large quantities of explosives to loosen the coal and facilitate its removal and separation from stone. To this "powder reek gastritis" is now added in some mines, where intensive coal-cutting by machines is in vogue, a severe irritation of the mucous membranes of the throat and lungs by the inhalation of mixed coal and stone dust.

ASPIRIN, PHENACETIN, AND DOVER'S POWDER.

DR. J. I. KUIT (Piet Retief, Transvaal) writes: In your issue of [illegible] (p. 628) Dr. Tressie Pires, when writing about aspirin, [illegible] powder for influenza, asks what [illegible] en. I have used this powder for about five years now, ever since I first saw the prescription in your columns. The effect in all forms of fever is good and in some cases almost magical. As a matter of fact, locally the people go to the chemist of their own accord to ask for "flu powders." The claim that was made for it originally, that it would cut short an incipient lobar pneumonia, I can fully endorse. The prescription was aspirin 5 grains, phenacetin 5 grains, pulv. ipecac. co. 5 grains. For children I give 2 to 5 grains, according to age—that is, from 2 years upwards.

TREATMENT OF ASTHMA.

DR. ROLF CREASY (London, W.) writes: Among the treatments proposed for asthma I have not seen any reference to static electricity. I would venture to suggest that great benefit is often derived from this method, which, within the last year or two, has been considerably enhanced by the combined use of infra-red rays. The aim of this treatment is restoration of a healthy condition of the respiratory tract.

MAP OF ROMAN BRITAIN.

DR. J. P. WILLIAMS-FREEMAN'S article in the *Journal* of May 18th (p. 922) on the new edition of the Ordnance Survey "Map of Roman Britain" has brought us inquiries from several readers. We understand that copies of this map can be obtained from H.M. Ordnance Office, Southampton, or through any of the leading booksellers in large towns.

A WARNING.

WE are informed by the superintendent of the Kent County Constabulary that the person described in the paragraph which appeared under the above heading in last week's issue (p. 1024) has been arrested, and on May 31st was remanded in custody for one week.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 73, 74, 75, 78, 79, 80, and 81 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 76 and 77.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 227.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

546. Hyperthyroidism and the Sympathetic Nervous System.

LEMOINE (*Le Scalpel*, April 20th, 1929, p. 421) remarks that it has been demonstrated that iodine is not necessary for the maintenance of the physiological activity of the thyroid, and that the effects of thyroid administration are due to the whole gland and not to any one of the isolated iodized substances—namely, iodothyrin, *thyroglobulin, and thyroxin.* After discussing the pathological anatomy of the gland and the effects on basal metabolism of intravenous injections of its total extract, the author states that all experiments indicate the importance of the thyroid in the nutritive exchanges, and that, though other endocrine glands are factors, it is usual to attribute variations in these exchanges to variations in thyroid functioning. According to his conclusions basal metabolism represents the activity of the organic sympathetic system, since it expresses the minimum output of energy necessary for the maintenance of life. The injection of thyroid extract causes a disequilibrium either of the sympathetic or the parasympathetic, or of both together, single injections producing hyper-excitability of the vagus, while after repeated injections symptoms of hyper-sympathicotomy appear. Each viscus possesses a sympathetic innervation, and this system includes automotor visceral ganglia and extra-visceral nerves. The ganglia ensure the automatic functioning of the organs and lie in their walls, while the nerves are connected with the sympathetic axial centres. Each organ has a double and antagonistic innervation from the central sympathetic and from the parasympathetic, each of which systems possesses an absolute and a relative tonus. Thus normal cardiac rhythm represents the relative tone of the heart and expresses the vago-sympathetic balance of that organ. The blood contains many substances, such as adrenaline and choline, which stimulate both systems and maintain the respective tonus of each; thus functional equilibrium is preserved. Changes in the composition of the blood modify this equilibrium, and the function of the internal secretions is to produce these changes. The author thinks it probable that changes in the thyroid and parathyroid secretions cause the sympathetic symptoms of exophthalmic goitre and tetany. Lemoine maintains that the absolute and relative tonus of the sympathetic nerves should be ascertained in these conditions, this giving valuable indications as to treatment. Hypertony with marked sympathetic predominance justifies operation on the sympathetic. Two cases of exophthalmic goitre are cited in which cure was effected by resection of the right upper cervical and left stellate ganglia, and in which the absolute tonus of the sympathetic was normal or increased, while that of the parasympathetic was entirely reduced.

547. Endemic Cretinism.

F. DE QUERVAIN (*Lyon Chir.*, [illegible] 1929, p. 5) points out that endemic cretinism and endemic goitre and is also allied to a f... of the thyroid gland, though all its manifestations are not explained by a simple hypothyroidism. In endemic cretinism, as in hypothyroidism, a lowering of the basal metabolism is found; also a slackening of all the vital functions, with arrested growth and a reduction of the cerebral functions. There are two types of cretin—those with or without goitre. The latter type, in which from birth or early infancy the children suffer from reduced thyroid activity, is sporadic rather than endemic, while goitrous children benefit during adolescence from the administration of thyroid gland, and may grow to a more normal height than the endemic cretin who has no goitre. The mentality of the cretin is usually childlike, optimistic, and contented, but the intellectual level is very low. Heredity is an important factor in cretinism, though it has not been determined whether it is due to insufficiency in the paternal or maternal parent. It is of interest to note that the skeleton of the cretin has many points in common with the primitive races of mankind, and is also very liable to develop disorders of nutrition, such as Perthes's disease of the head of the femur, osteochondritis dissecans of the condyles of the femur, with the formation of free bodies in the joint and early types of arthritis deformans. Where possible those children afflicted with complete or partial cretinism should be educated in special schools and afterwards segregated in homes where they are only required to do light work in the house or out of doors. Treatment should comprise the administration of thyroid gland extract by mouth, or by injection, or the grafting of a healthy thyroid gland, but complete recovery is not possible. It has lately been suggested that iodine incorporated with the diet may be a preventive method of reducing the number of cretins which, in certain districts, has not decreased in the last forty years. The most simple method of administering this is in the salt used for cooking, the average amount being about 5 mg. of potassium iodide per kilogram of salt, and may be given to the whole population of a cretinous district. At least twenty years would have to elapse before results could be judged.

548. Epididymitis following Typhoid Fever.

G. GREENBERG and M. GREENWALD (*Journ. Amer. Med. Assoc.*, March 23rd, 1929, p. 983), who report a personal case, state that while epididymitis in the course of or in convalescence from typhoid fever is rare, only 102 cases having been reported up to 1909, no previous example had been published of a case which developed four years after typhoid. Their patient was a man, aged 58, who contracted typhoid fever in 1924, complicated by cholecystitis. A year later he had another attack of cholecystitis of a week's duration. For the two years following the attack of typhoid the stools yielded positive cultures, but subsequently became negative. In December, 1927, he had another attack of cholecystitis which lasted only a short time. In October, 1928, he had a fourth attack, and, after subsidence of the gall-bladder symptoms, developed acute epididymitis on the right side. The Widal reaction was positive in 1 in 100, but the stools were negative. Of the 102 cases of epididymitis on record, 17 developed during the height of the fever and 71 in convalescence, while in the remainder the time was not recorded. In 31 the testes alone, in 10 the epididymes alone, and in 43 the epididymes, testes, and cord were involved. Suppuration occurred in 22 instances, and in many cases atrophy of the testes followed. The authors recall that Widal recovered the typhoid bacillus from the testes in many cases of typhoid fever at necropsies.

549. Toxin-antitoxin and Hypersensitiveness to Therapeutic Serum.

J. E. GORDON and S. M. CRESWELL (*Journ. Preventive Med.*, January, 1929, p. 21), as the result of studying 1,556 consecutive cases of diphtheria, of which 283 patients had received toxin-antitoxin, 90 had had previous injections of serum, and 1,183 gave no definite history of injections of horse serum, came to the following conclusions. The majority of persons immunized with toxin-antitoxin mixtures (74.1 per cent.) had serum reactions after subsequent therapeutic serum, as compared with only 18 per cent. of persons not so sensitized and 43 per cent. of persons who had had previous injections of serum. One dose of toxin-antitoxin produced a sensitizing effect comparable to that indicated by a single dose of serum (42.1 per cent.). Reactions from therapeutic serum given after toxin-antitoxin were generally more severe, and included more immediate reactions than after previous serum injections, while reactions in non-sensitized persons were the mildest in type.

Surgery.

550. Lumbo-sacral Backache.

C. E. AYERS (*New England Journ. Med.*, March 21st, 1929, p. 592) illustrates this subject with a series of *x*-ray photographs and reproductions of dissections, and gives an account of 36 cases treated by immobilization of the lumbo-sacral joint by Hibbs's method. The author considers that pathological conditions of the lumbo-sacral joint constitute a more important cause of backache than those of the sacro-iliac joint, and he emphasizes the following anatomical points. (1) There is here a junction between the freely mobile spine and the fixed sacrum. (2) There is a variable "shearing force" according to whether the superior surface of the sacrum is more vertical or horizontal. (3) The articulation in this region (as apart from the synchondrosis) is by two bony facets, the shape of which is liable to alteration by strains; there is, hence, a liability to injury of the fifth (and largest) nerve root, which lies anteriorly to the posterior articulation between the fifth lumbar vertebra and the sacrum. The space between the articular facet and the intervertebral disc is only just large [illegible] the emergence of the nerve

(4) A considerable length of the nerve trunk is unprotected by the arachnoid. Since the publication of an earlier paper in 1927 Ayers has had replies to a questionary from 36 patients treated by operation, and has made a careful analysis of clinical findings, *x*-ray results, and post-operative progress. He considers that the classical signs of lumbo-sacral disease are: a "list" to the affected side; tenderness at the lumbo-sacral junction, unless masked by contraction of the erector spinae; tenderness over the back of the trochanter in the region of the gluteal fold; burning pain felt down the outer side of the thigh, corresponding to the tensor muscle, and, in the severer cases, down the outer side of the calf and beneath the external malleolus to the dorsum of the foot. Backache was present in all Ayers's 36 cases; in 17 there was pain down one leg, and in 4 cases there was pain down both legs. In all cases *x*-ray examination showed either arthritic changes in the articular facets or thinning of the intervertebral cartilage (the latter in 26 cases). In one case there was sacralization of the fifth lumbar vertebra and arthritic changes in the fourth and fifth lumbar facets. Immobilization was always performed by Hibbs's method of arthrodesis between the articular facets of the fifth lumbar vertebra and the sacrum, and also between the fourth and fifth lumbar vertebrae if arthritic changes were present. After ten days in bed without any appliance the patients were fitted with a plaster jacket, a pelvic belt, and straps to secure backward rotation of the pelvis, and so to bring the upper bearing surface of the pelvis as near the horizontal plane as possible; after another six weeks a spring "back-brace" to include the shoulders was fitted. In 13 cases relief from all pain was immediate; in 4 it was found in three to six weeks; in 15 in three to six months; and in 2 in one year. In only one case was no relief at all obtained. No patients operated on before January, 1928, are included in the series; 27 of the patients are engaged in work as hard or harder than before, and 8 in lighter occupations. Ayers lays particular stress on the frequency with which pain typical of "sciatica" was complained of before operation.

551. Latent Cancer.

F. G. GADE (*Norsk Mag. f. Laegevid.*, April, 1929, p. 354) states that during the period 1908-27 in 1,618 necropsies at Oslo City Hospital malignant tumours were discovered. Of these, 183, or 11.4 per cent., were casual findings, and had not been diagnosed during life, while 154 were *carcinomata* with the following distribution: stomach (76 cases), intestine (23 cases), prostate (13 cases), liver and gall-bladder (10 cases), uterus (8 cases), pancreas (7 cases), oesophagus (6 cases), lungs (6 cases), bladder (2 cases), various sites (3 cases). Of the other growths, 5 were gliomata, 1 [illegible] and 6 sarcomata. It was a remarkable [illegible] cent. of the latent cases were found in men, though cancer in Norway is usually preponderant in women. Gade concludes that the return of deaths from cancer in Norway as given in the official statistics should be somewhat increased to give a correct impression of the incidence of the disease in that country, first by 12 per cent. to represent the latent cases, the number of which is likely to be greater away from cities and hospitals, and, secondly, by a figure ranging from 0.8 to 16.7 per cent. to express the percentage of deaths of which the cause was unknown in the rural parts of each county.

552. Surgical Treatment of Quinsy.

D. DE LAMOTHE (*Arch. Int. de Laryngol.*, February, 1929, p. 216) emphasizes the difficulty of successfully opening a peritonsillar abscess when complicated by trismus, and claims that all such cases should be operated upon under general anaesthesia. He describes his own technique, which, he states, has always been successful in his hands. The author inserts a closed Doyen gag between the teeth, and induces anaesthesia with ethyl chloride. The mouth is then widely opened and the throat examined with reflected light. In this way the exact position of the abscess can be seen and the most favourable position for incision selected. Before incision the patient's head is strongly turned to the side opposite to the abscess, and in this position the author claims that no pus or blood can enter the air passages.

553. Recklinghausen's Disease.

L. FECI (*La Chir. degli Organi di Movimento*, January, 1929, p. 235) publishes two cases of this disease, one generalized and the other localized. The main features of the disease are brown tumours, pseudo-cysts, bony deformity, and hyperostosis; of these the cysts are the most characteristic element, hence the great importance of radiography in the diagnosis of these cases. The author discusses fully the differential diagnosis from Paget's disease, osteomalacia, and late rickets. Paget's disease attacks older people, frequently [illegible] the cranium, and is often associated with calcified [illegible]; moreover, the radiographic appearance is very different. The localized form has to be distinguished from new growths such as sarcoma or enchondroma, and from abscess or myeloplaxic tumours. As regards etiology, Feci remarks that trauma will not explain multiple cysts, and of the various theories put forward the only one he is inclined to accept is that which is based on changes of calcification of the bone due to defects in the circulation. In one case a weak culture of *Staphylococcus albus* was made from material removed from the bone, but the patient showed no signs of inflammation and her temperature was never above the normal.

Therapeutics.

554. Gold Salts in Lupus.

W. COLE (*Canadian Med. Assoc. Journ.*, April, 1929, p. 372) observes that, though Koch discovered in 1890 the inhibiting effect of gold compounds in high dilutions on the growth of tubercle bacilli, the use of these substances in the treatment of lupus is comparatively recent. The gold salt most commonly used in this dermatitis is gold and sodium thiosulphate, and the results obtained by various authors are cited. Cole reports a case of typical lupus erythematosus in which complete cure was obtained by the use of this drug. The condition commenced in 1917, and, despite treatment with the quartz lamp, carbon dioxide snow, and *x* rays, gradually grew worse during the following ten years. Gold treatment by intravenous injections of sanocrysin was then instituted, the initial dose being 50 mg. After five months the eruption completely disappeared, the nose is practically well, and normal sensation has returned over the whole area previously involved. The patient received eighteen 50 mg. doses and ten of 100 mg. of sanocrysin. No general reaction occurred after the fourth dose, and at no time was there any immediate severe reaction. The general condition was excellent throughout treatment, which evidently had a tonic effect. In contrast with this, J. F. BURGESS (ibid., p. 392) reports a case of lupus erythematosus in which this salt produced no benefit, but a local activation and acute extension of the disease followed its administration. The drug was therefore discontinued, and intramuscular injections of a 3 per cent. solution of sodium morrhuate substituted for it with striking results. In four months the lesions completely involuted, leaving a mild pigmentation at the side of the plaques and a fine atrophy in some of the older, thicker areas. The initial dose of 0.5 c.cm. was gradually increased to 3 c.cm.

555. Quinine in Pneumonia.

LOLITA M. FLEWELLING (*Med. Journ. and Record*, April 17th, 1929, p. 446) calls attention to the prophylactic and therapeutic action of quinine in pneumonia. By the comparatively painless intramuscular injection of a preparation containing a 3 per cent. oily solution of quinine with camphor and the terpenes a means is afforded of administering basic quinine alkaloid. Within a few minutes of the injection a marked odour of terpenes appears in the breath, pointing to the fact that the drug is conducted to the lungs, where it exerts a considerable antibacterial effect. The author's experience confirms the suggestion that the concentration of quinine in the lungs by such methods is capable by its antibacterial effect of producing favourable reactions in infections and even in tuberculosis; it is said to be of considerable value in prophylaxis and treatment in the earliest types of broncho-pulmonary infection, especially those occurring in influenza. From experience in 27 cases of acute influenzal broncho-pulmonary infections treated with such intramuscular injections it was found that the majority of patients began to improve clinically with the initial dose, and so uniform were the results that a fall in the temperature was the rule after the first injection. These observations agree with those of other observers, and the author hopes for further investigation of the method both as a prophylactic against pneumonia and in the treatment of pulmonary infections.

556. Radiotherapy for Acute Epidemic Encephalitis.

U. NUVOLI (*Il Policlinico*, Sez. Med., April 1st, 1929, p. 177) has treated eighteen cases of epidemic encephalitis in the acute stage with *x* rays. The author finds that to obtain good results the treatment should be commenced as early as possible; the best results were obtained in those cases which were subjected to the *x*-ray therapy within the first fifteen days of the disease; probability of success is lessened if treatment is delayed for a month, and the chances of complete cure are greatly diminished if the lesions are severe. Strong doses were employed—a spark equivalent to 40 cm., an intensity of 2 milliamperes, filtered through 0.5 mm. of zinc and 4 mm. of aluminium, and a focal distance of 23 cm. Having determined the size of the lesion, the radiations were

made to converge as near as possible towards the basal ganglia of the mesencephalon, and to a number of areas 4 by 4 cm. each was administered three-fourths of the erythema dose. The convergence of the rays to the mesencephalon is attained by suitable inclination of the tube to each area. Immediately after the radiation the subjective symptoms are aggravated; there is intense headache, severe vomiting, and raised temperature which persists for five to six days, but need not arouse anxiety. After these more or less severe manifestations have passed the patient commences a gradual and continuous convalescence.

557. Carbon Dioxide Therapy in Hypostatic Pulmonary Congestion.

R. E. BURNS and W. S. MIDDLETON (*Amer. Journ. Med. Sci.*, April, 1929, p. 564) report that in cases of hypostatic pulmonary congestion occurring in the aged and debilitated, as the result of the depressed respiratory motility, the intermittent inhalation of carbon dioxide brings about apparent relief if it is used sufficiently early. The rate and duration of the administration are controlled by the respiratory response and the comfort of the patient. The authors remark that it is important to distinguish between pulmonary stasis resulting from respiratory depression and that which is dependent upon the failure of the right side of the heart, since the use of carbon dioxide inhalations might be strongly contraindicated in the latter condition. Moreover, these inhalations are inadvisable when bronchitis or pneumonia is present, since they may lead to dissemination of infection. The authors suggest that it seems possible that there is some prophylactic value in these inhalations which might well be remembered in any surgical cases which seem to require them.

558. Protein Therapy in Psychoses.

ACCORDING to A. J. ZÁVODNY (*Bratislavské Lekarské Listy*, April, 1929, p. 266), many cases of psychosis are caused by toxicoses, anomalies of the metabolism, and disorders of the endocrine functions. On this assumption he tried injections of typhoid vaccine in twenty cases of general paralysis and in eighty cases of other psychoses with considerable success. The author states that several patients with psychoses were clinically cured, and he adds that in general paralysis the results were as good as those of the malaria treatment. The author attributes the beneficial effects to the active hyperaemia which follows the treatment, increasing the endocrine activity, and favouring detoxication and consequent regeneration of the affected cerebral parenchyma.

Disease in Childhood.

559. Spasmophilic Infantile Convulsions.

P. FONTEYNE (*Le Scalpel*, April 27th, 1929, p. 441) states that infantile spasmophilia or tetany chiefly occurs between the ages of 3 months and 2 years, though cases are sometimes observed in nurslings and at puberty. In primary tetany of the second and older infancies a constitutional neuropathic state is much more evident than in that of nurslings, and thus there is a distinction between the two forms. The latter, the most frequent and often complicated by convulsions, is alone dealt with. Infantile tetany is observed particularly during winter and spring, and seems to have a predilection for the Teutonic and Anglo-Saxon races. As in adult tetany, the infantile form is characterized by a hyper-excitability of the nerves, which is manifested by various isolated or associated symptoms, such as general, or more often localized, muscular contractions; glottic spasm; gastric spasm; and general or partial convulsions. Various pathogenic factors have been suggested as the cause of spasmophilia, including hypocalcaemia, toxins, solar deficiency, and avitaminosis D. A diminution of the blood calcium has often been noted in this disease, and, as tetany is almost always associated with rickets, a disturbance of calcium metabolism is apparently a cause. The occurrence of the malady in poorly nourished infants and in those with gastro-intestinal troubles supports the toxic theory. In spasmophilia the convulsions occur unexpectedly and without apparent cause. Two pathognomonic symptoms are glottic spasm and the sign of Chvostek, which consists in a contraction of the peribuccal muscles and even of all the muscles of homonymous hemi-face or of the entire face obtained by percussion of the facial nerve midway between the otic lobule and the labial commissure. Other signs, such as those of Schultze and Weiss, are mentioned. Electrical reactions are obtained with weaker currents than normally, and a state of chronaxy, characterized by unstable nervous excitability, exists. The prognosis is usually good, though certain authors affirm that infantile tetany predisposes to epilepsy. The most efficient treatment consists in the administration of large doses (6 to 8 grams in 24 hours) of calcium chloride, and in a basic treatment with ultra-violet rays. This may be supplemented with pure, non-medicated cod-liver oil, and good hygienic conditions should be maintained. In urgent cases the usual sedatives (bromides, chloral, gardenal) have been found less effective than calcium salts. The irradiated stearines have also been of little avail in the general treatment.

560. Diabetic Children.

BASING their deductions on an extensive study of diabetic children, E. P. JOSLIN and PRISCILLA WHITE (*Journ. Amer. Med. Assoc.*, January 12th, 1929, p. 143) state that diabetes may be latent in the ancestor when it has appeared in or caused the death of the offspring, and that all diabetes in children may be hereditary; the incidence of a diabetic heredity increases with the duration of the disease and the number of relatives. In twenty-two months the total mortality among 303 diabetic children was 6, or 1 per cent. a year. Coma is almost the only cause of death, and represents neglect. With insulin (10 to 40 units every half-hour until the urine is nearly sugar-free), with gastric lavage for a dilated stomach, salt solution by the rectum, subcutaneously or intravenously, and caffeine for the heart, coma should be averted or conquered. The present condition of the surviving children is good, but those in whom the disease is of long duration usually show glycosuria, which most commonly appears after breakfast and disappears by noon. The best preventive is to give insulin an hour before breakfast, or, if the urine is not sugar-free on rising, to administer 2 to 5 units on retiring the preceding night. Additional aids are a low carbohydrate content at breakfast and a few minutes' exercise before it. Diabetic children mature sexually, and though one-third of the cases remain underweight, this is due to lack of close supervision, a pretuberculous state, or the onset of the disease before the use of insulin. As regards complications, cataracts have not as yet been recognized, arterio-sclerosis was noted in only 5 out of 29 children with a disease duration of five years or more, and in no case was death due to tuberculosis. Among characteristic features of the disease is excessive height at the onset in contrast to overweight in adults. Diabetic children resist all types of infection if there is proper adjustment of diet and insulin. Confusion between coma and appendicitis is easy and serious; if there is any doubt an operation should be performed. The blood cholesterol, a true index of the other lipoids, is below rather than above the normal. Insulin reactions are distressing but hardly ever fatal, and are far less frequent than might be expected. A child with non-diabetic glycosuria appears to conform to that diagnosis in the vast majority of cases.

561. Dermatitis Gangraenosa Infantum.

MULTIPLE disseminated gangrene of infants is a rare and often fatal infection according to C-K. HU (*National Med. Journ. of China*, April, 1929, p. 149), who reports a case in which *Salmonella suipestifer* was isolated from the blood. The majority of cases of gangrenous dermatitis occur in children under the age of 3 years; it apparently affects the well-nourished as well as under-nourished infants, although lowered vitality has been emphasized as a predisposing factor. Other causes have been suggested by various authors, such as tuberculosis, syphilis, and rickets. The lesions may start as vesicles or papules, followed by scab formation in the centre with ulceration at the periphery. Systemic disturbance with fever, leucocytosis, albuminuria, pneumonia, pulmonary abscesses, and pus in the pleural and pericardial cavities have been observed in different cases. In the present one, a male child, aged 25 months, a transient generalized erythema appeared a few days before the onset. Numerous pustules, abscesses, and ulcers, but no vesicles, were noted, especially on the lower jaw and face, a few being found on the scalp, neck, trunk, arms, and legs. These ulcers were discrete, oval or round, with sharp, perpendicular edges. Most of the ulcers penetrated the whole thickness of the skin. In the centre of each was a gangrenous, dried, and adherent scab with an ulcerated zone, discharging foul-smelling pus, at the periphery. There was practically no inflammatory areola. The blood Wassermann test was negative. General treatment, together with local antiseptic applications, resulted in only temporary improvement, and the patient died in about three weeks. The necropsy revealed a bronchopneumonia with multiple pulmonary abscesses and a few haemorrhagic areas. The condition at first suggested smallpox, but the history and course of the case contraindicated this. Syphilis was seen not to be the cause, and, though it is admitted by Hu that there is no proof that the ulcers were directly due to the organism isolated, yet he thinks that the poor general condition and the bacteriaemia may have been predisposing causes of the dermatitis.

Obstetrics and Gynaecology.

562. Induction of Labour at Term.

M. WIDERA (*Zentralbl. f. Gynäk.*, February 16th, 1929, p. 403) records 44 cases in which an attempt was made to induce labour by the administration of castor oil and pituitary extract. All the patients were at or beyond term, and induction was tried either because of foetal post-maturity or for economic reasons. The cases of foetal post-maturity were mostly those of multiparae whose previous gestations had been abnormally prolonged. In the other cases term had been reached and the patients, being anxious to return to their home duties, sought the clinic that labour might be expedited. The procedure adopted, which consisted in the administration of two teaspoonfuls of castor oil, followed an hour later by quarter- or half-hourly subcutaneous injections of small doses of one or other of the pituitary extracts, was successful in three-quarters of the cases. The advantages which have been claimed for this treatment are that it is devoid of danger for the mother and foetus, that it curtails considerably the duration of labour even in primigravidae, and that the third stage of labour is shortened and relatively devoid of haemorrhage.

563. Spinal Anaesthesia in Artificial Induction.

WEYMEERSCH, POULAIN, WODON, and DE GUCHTENEERE (*Bruxelles-Medical*, April 14th, 1929, p. 579) report observations on a series of thirteen cases in which full-term pregnancy was terminated by manual dilatation and forceps under spinal anaesthesia by the method of Delmas. The conditions present were commencing eclampsia, uterine hypotonus, cardiac insufficiency, twins with hydramnios, and complete breech presentation. The anaesthetic used was scurocaine (3 c.cm. of a 4 per cent. solution on three occasions) and tutocaine in powder dissolved in 3 to 5 c.cm. of cerebro-spinal fluid for the remainder. The anaesthesia obtained was uniformly good. Within ten to twenty minutes the vulva and perineum were very markedly relaxed, and the cervix also became supple usually. In cases where there had been previous infection of the cervix, or in which there was cicatricial tissue, the response of the cervix was not so good. These two conditions appeared to be contraindications since tears were likely to result. Manual dilatation was most easily and rapidly performed when normal dilatation had already started. Hypertonus was noted to a greater or less degree in all cases, and to this condition was due the difficulty of performing version. Out of five attempts only three were successful, and in two of these there was hydramnios, which facilitated manœuvres. The puerperia were without incident. There was one case of foetal mortality due to an infected cervix which was not recognized before the procedure was undertaken. All patients were examined for tears; there was one serious one from the cervix to the fornix, three small lateral cervical tears, two bilateral cervical tears, and two small perineal ones. The authors conclude that the use of spinal anaesthesia for artificial induction is to be advocated, but that the contraindications must be strictly observed.

564. Uterine Scars after Cervical Caesarean Section.

J. P. GREENHILL and B. BLOOM (*Journ. Amer. Med. Assoc.*, January 5th, 1929, p. 21) record a study of the histological characters of old uterine scars. In 37 instances, at the time of a repeated Caesarean section, a piece of tissue was removed from the site of the previous incision in the lower uterine segment; in 16 of these the scar was visible to the naked eye. A control observation was arranged by removing a portion of the lower uterine segment from six patients at the time of a first laparo-trachelotomy. The sections were stained by the Weigert-van Gieson method. The results were divided arbitrarily into four groups: those which showed no scar tissue at all (6 cases); those with undoubted scars in the old incision, but in which the integrity of the uterine wall remained essentially unchanged (21 cases); and those in which the changes were striking and consisted of marked thinning of the uterine wall (5 cases). From a review of the literature on cervical operations and from their own investigation the authors suggest that an anatomically weak scar does not necessarily presuppose inability to withstand the distension caused by pregnancy or the strain of labour. An association was noticed between bad scars and the fact of the patient being in labour at the time of the first operation. Oedema and an appearance of stretching were found in a large number of specimens, and were more marked in the densely fibrous scars. As this appearance was also present in the normal uteri, the authors suggest that it is due to varying degrees of tension exerted on the lower uterine segment before and during labour.

Pathology.

565. Functional Relations of the Spleen and Liver.

G. MONTEMARTINI (*Il Policlinico*, Sez. Chir., February 15th, 1929, p. 70) has examined the effect of splenectomy on the functions of the liver. Employing dogs, he found that splenectomy after the administration of ox bile was in no case followed by the appearance of bilirubin in the blood or urobilin in the urine. Experiments for the estimation of nitrogen metabolism were made on four rabbits and three dogs; after removal of the spleen all the animals showed marked fall in body weight, a diminution of the daily amount of urine passed, an increase in the total nitrogen and urea, a diminution in the nitrogen from ammonia and amino-acids, and an increased nitrogen-urea coefficient. A number of observations on the carbohydrate metabolism demonstrated a rise in the amount of glycogen in the liver and in the alimentary hyperglycaemia. From these experiments and also from clinical observation the author affirms a functional correlation between the spleen and the liver in the sense that the healthy spleen has a regulating action on the various functions of the liver. He concludes that before removing the spleen in the human subject it is necessary to investigate fully the functioning of the liver, especially with regard to the nitrogen and carbohydrate metabolism.

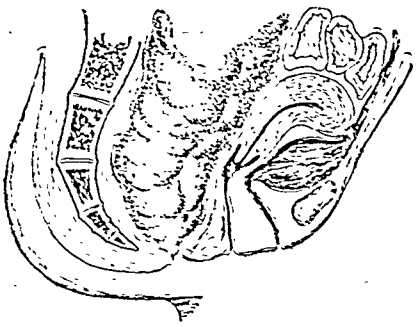
566. Serum Diagnosis of Cancer.

B. GRUSKIN (*Amer. Journ. Med. Sci.*, April, 1929, p. 476) advances the hypothesis that each type of normal cell produces a lysin against other types of cells; that is to say, connective tissue cells normally have the property of generating lysins which are antagonistic to excessive growth of epithelial cells, so that, although an inciting factor may be present, carcinoma does not develop. If this lysin is not produced, cancer results when the proper extrinsic factors are present. The opposite cycle also occurs, and if there is a deficiency or lack of lytic agent normally produced by epithelial tissue, sarcoma will result. Based on this conception of the possible cause of malignant disease, Gruskin believed that a lytic agent might be produced by the inoculation of animals with purely embryonic epithelial cells in the case of carcinoma, and connective tissue cells in sarcoma. In this way amboceptors would be developed in the treated animals, and their serums might have the property, when injected into a patient with malignant disease, to destroy epithelial or connective tissue cells in carcinoma or sarcoma respectively. Having demonstrated the specificity of the amboceptor thus produced, the test was used for diagnostic purposes. The technique of the test when amboceptor was used and its modification with alternative use of antigen is described. Of 138 cases of known malignant tumour, only 3 yielded negative reactions; 369 cases of known non-malignant disease gave 12 positive reactions; and 146 normal cases showed 143 negative and 3 faintly positive results. Gruskin maintains that these results prove the test to be of practical importance in the serum diagnosis of carcinoma and sarcoma.

567. Epizootic Lymphadenitis in Guinea-pigs.

E. MEGRAIL and R. N. HOYT (*Journ. Infect. Dis.*, March, 1929, p. 243) describe an outbreak of epizootic lymphadenitis that occurred in the stock of a dealer. Thirty-five guinea-pigs with unruptured abscesses were received for examination, besides a number with draining abscesses or with scars of healed lesions. The abscesses, which varied from 1 to 6 cm. in diameter, were situated mainly in the anterior cervical region, but in a few animals other regions of the body were affected. On aspiration a thick white pus was obtained, which showed the presence of Gram-positive cocci and degenerated leucocytes, mostly of the mononuclear type. From every animal but one examined streptococci of the β or γ type were found in conjunction with staphylococci; in the single exception streptococci alone were present. Experimental inoculation subcutaneously with pure cultures of the streptococci gave rise to abscess production in from seven to thirty-seven days, and from the lesions streptococci were isolated together with staphylococci. Experimental inoculation with staphylococci failed to cause abscess formation. The authors therefore conclude that the primary cause of the natural disease is a streptococcus, and that staphylococci act merely as secondary invaders. The mode of infection was not ascertained with certainty. Feeding experiments with cultures of streptococci, either with or without concomitant injury to the mouth, and inhalation experiments, failed to reproduce the disease. On the other hand, in a certain number of animals inoculated on the skin by the scratch method typical abscesses developed.

The Menace of the Overloaded Bowel



always present, easily becomes serious in women. It causes interference with the pelvic circulation and tends to produce congestion of the uterus, not infrequently followed by functional disorders, producing dysmenorrhœa, menorrhagia, and even inflammatory conditions.

AGAROL Brand Compound gives relief and frequently permanently restores the functional activity of the colon. One tablespoonful before retiring, gradually decreased as improvement takes place, is especially well adapted for the treatment of constipation in women; because of the gentle action of Agarol Brand Compound and absence of irritation from its use.

A liberal trial quantity at the disposal of physicians.

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification, stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Mustard Plasters or Ultra-Violet?

Specialists have defined the general effects of Ultra-Violet irradiation as:—

Increased metabolism.
Improved appetite and sleep.
Marked mental stimulation.
Reduction of pain.
Deepening and slowing of respiration.
Reduction of blood pressure.

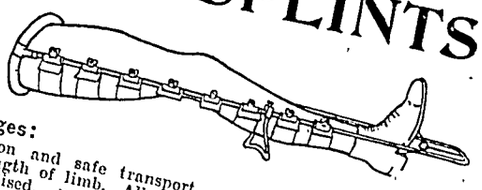
COLLENDER'S SPLINTS

Combine the advantages of the Thomas Splint with many improvements and additions.



(Patented in many Countries)

Advantages:

They ensure accurate extension and safe transport. They are adjustable to any length of limb. All parts are interchangeable, standardised, numbered, and replaceable. Being made of metal—Duralumin—they combine great strength with very light weight. They are untarnishable, and can be immersed in sterilizing fluid without injury. They can be used repeatedly.

They are supplied in fitted cases. The larger set provides material for treating ten fractures simultaneously.

Invaluable for Hospital Emergency work, particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

Full particulars from:

MR R.H.DENT'S ARDENTE FOR DEAF EARS

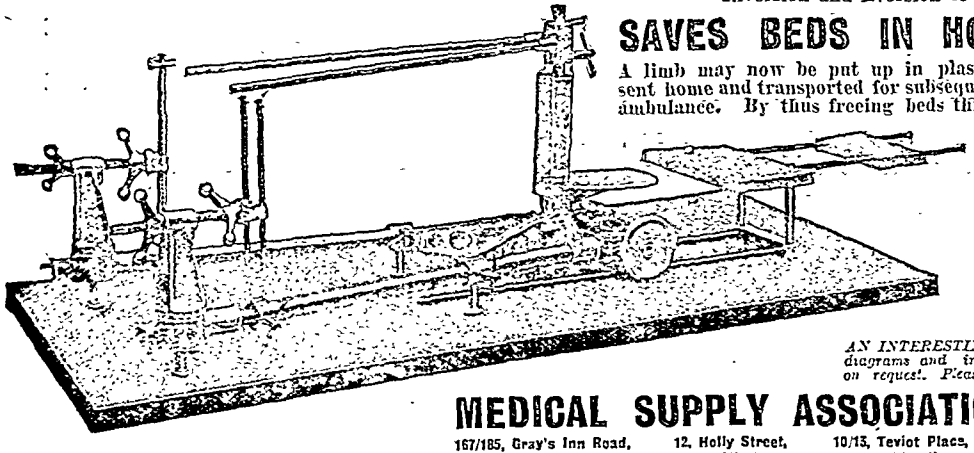
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. × 14 in. × 7 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

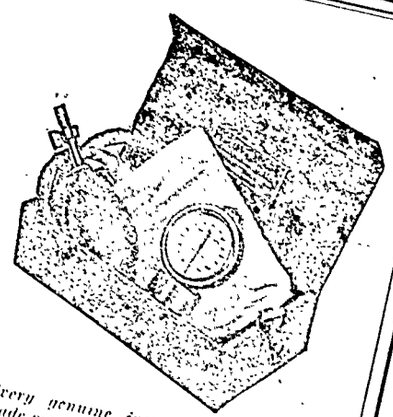
As Necessary as a Stethoscope

The present-day physician can ill afford to dispense with a sphygmomanometer as part of his visiting equipment. Many of the greatest medical minds of to-day advocate blood pressure tests as a guide to the eventual diagnosis.

The question of portability is easily solved by the S. & M. Portable type of Sphyg. as illustrated. This instrument—including Patent Arm Sleeve and Inflating Bulb with Control Valve—is contained in a leather carrying case 7 in. long, 4 in. wide by 3 in. deep.

Write for full details and prices.



Every genuine instrument bears the trade mark "Tycos" engraved on the dial.

Greater Comfort for Your Patients.

"The Rose Corset-Belt"

which has set a new standard and proved so effectual in all abdominal cases where support is required. The X-rays have shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

PEACE

Evening. A faint rustle in the trees. A few notes, melodious and low, from a night songster. In the garden world and worry is forgotten. In lazy comfort, sheltered from winds, one may talk a little, smoke a little, or drift into a blessed silence. Only nature will be busy; dosing the body gently with pure fresh air.

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the natural tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 12/- bottles.

Special Terms to Hospitals.

A CHALLENGE TO NEURASTHENIA

A patient's account of the treatment given by the late Dr. L. S. Barnes, O.B.E., of Whitwell, Herts.

"The book has opened up a new train of ideas in the treatment of the neurasthenic. I congratulate you . . . on the stimulus you have given towards a better understanding of this difficult subject. It will be a permanent help to the profession, and has brought to light valuable work which would otherwise have been allowed to pass unnoticed."
F.R.C.S., Eng.

"Interesting and valuable. . . . Described so convincingly and with real psychological insight."
M.B., Ch.B., Medical Psychologist.

"There is not the slightest doubt to my mind of the value of the work both to busy practitioners like myself and to those suffering from neurasthenia."
M.D., Oxon.

HARROGATE CORPORATION

F. J. C. BROOME,
General Manager of Wells and Baths.

The Royal Baths,
HARROGATE.
June, 1929.

Dear Sir,

An Invitation to Visit Harrogate

We are constantly advertising that Harrogate is a BRITISH Spa offering a "Cure" and a Holiday unsurpassed at any Foreign Resort, but unfortunately, advertising not being altogether free from exaggeration, our claims may leave you unconvinced.

To prove our point and to gain your goodwill for a BRITISH Spa we ask you to pay Harrogate a visit to satisfy yourself as to what we are doing and how we do it!

If you will send a postcard, a list of the concessions we ask you to accept during your stay, and Medical and "Lay" Literature, etc., will be sent you by return of post.

I am,
Yours truly,
F. J. C. BROOME,
Spa Manager.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS, NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No 55 Northampton), who can be seen in London by appointment.

HAYDOCK LODGE
NEWTON-LE-WILLOWS, LANCASHIRE.

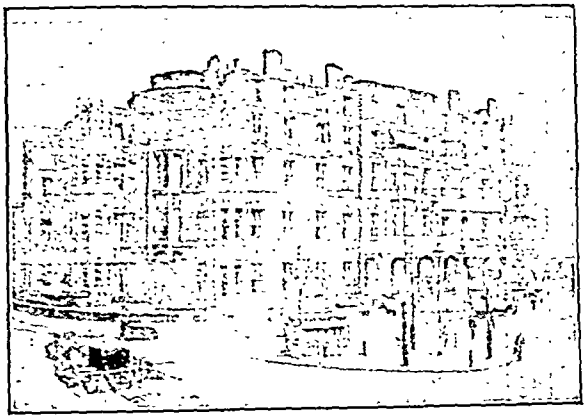
SPECIAL COURSE IN THE RADIUM TREATMENT OF CANCER



A Practical Course in the Radium treatment of Cancer, designed for Medical Men who have recently had, or are about to have, Radium put at their disposal, will be held at the Westminster Hospital from July 29th to August 3rd, 1929.

Details of the Course, for which the fee will be ten guineas, may be obtained on application to the Dean, A. S. WOODWARK, C.M.G., C.B.E., M.D., F.R.C.P., Westminster Hospital Medical School, 12, Caxton Street, S.W.1.

THE UNIVERSITY OF LIVERPOOL.

FACULTY OF MEDICINE.

THE MEDICAL SCHOOL provides complete courses of instruction for the Examinations of the University of Liverpool, and also meets the requirements of other Universities and Examining Bodies in the United Kingdom.

Other Schools of the Faculty are:—The School of Dental Surgery, the School of Hygiene, the School of Tropical Medicine, and the School of Veterinary Science.

DEGREES AND DIPLOMAS IN THE FACULTY OF MEDICINE.

Bachelor of Medicine & Bachelor of Surgery	M.B., Ch.B.
Doctor of Medicine	M.D.
Master of Surgery	Ch.M.
Master of Hygiene	M.H.
Master of Orthopædic Surgery	M.Ch.Orth.
Bachelor of Dental Surgery	B.D.S.
Master of Dental Surgery	M.D.S.
Bachelor of Veterinary Science	B.V.Sc.
Master of Veterinary Science	M.V.Sc.
Doctor of Veterinary Science	D.V.Sc.
Doctorate in Philosophy	Ph.D.
Licence in Dental Surgery	L.D.S.
Diploma in Public Health	D.P.H.
Diploma in Tropical Medicine	D.T.M.
Diploma in Tropical Hygiene	D.T.H.
Diploma in Veterinary Hygiene	D.V.H.
Diploma in Medical Radiology & Electrology	D.M.R.E.

Valuable Fellowships, Scholarships, and Prizes are offered for competition each year.

THE CLINICAL SCHOOL consists of FOUR GENERAL HOSPITALS: The Royal Infirmary, the Royal Southern Hospital, the David Lewis Northern Hospital, and the Stanley Hospital; and of FIVE SPECIAL HOSPITALS: The Eye and Ear Infirmary, the Hospital for Women (including the Samaritan Hospital), the Royal Liverpool Children's Hospital, the Liverpool Maternity Hospital, and the St. Paul's Eye Hospital.

These Hospitals contain in all about 1,500 Beds.

The organization of these Hospitals to form one teaching Institution provides the Medical Student and Medical Practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom.

Infectious Diseases are studied in the Local and District Hospitals, and Mental Diseases at the County Mental Hospital, Rainhill.

For information on all matters concerning the curriculum application should be made to the Dean of the Faculty of Medicine, the University of Liverpool.

W. J. DILLING, Dean.

EXTERNAL EXAMINERSHIPS, 1930.

The Senate announce the following vacant External Examinerships for all Examinations above Matriculation for the year 1930. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included.

The Examiners for the Final Examinations will be invited as occasion arises to take part in the Higher Examinations, but the Senate have resolved that in certain cases in which the work is heavy they shall not be required to do so.

For the First Examination for Medical Degrees.

Biology. Chemistry. Physics.

For the Second Examination for Medical Degrees

Anatomy (two). Pharmacology. Physiology

NOTE. One of the two Examiners appointed in Anatomy will be required to act for Science Examinations also

For Final and Higher Examinations for Medical Degrees.

Medicine Surgery (two). State Medicine.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable on or before Monday, July 7th, 1929. (Envelopes should be marked "Examinership")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

University of London, June, 1929. T. FRANKLIN SIBLY, Principal. South Kensington, S.W.7.

O. C. HOWELLS, Secretary.

County Borough of Birkenhead.

MEDICAL OFFICER'S DEPARTMENT.

ASSISTANT MEDICAL OFFICER (Resident).

Applications are invited for the above appointment from duly qualified men (unmarried) holding a Diploma in Public Health, who have had experience as residents in Hospitals for Infectious Diseases.

The appointment carries with it a salary of £450 per annum, residence at the Infectious Diseases Hospital, board and washing.

The successful candidate will be required to pass a medical examination, and a deduction of 5 per cent. will be made from salary towards the Council's scheme under the Local Government and Other Officers Superannuation Act, 1922.

He will be required to undertake the treatment of patients in the Hospital, to assist at the Municipal Venereal Diseases Clinic, and to carry out such other duties as may be assigned to him by the Medical Officer of Health.

Canvassing members of the Town Council, either directly or indirectly, will disqualify.

Particulars of the appointment and form of application may be obtained from D. MORLEY MATHIESON, Esq., M.A., M.D., Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Applications must be received not later than June 17th.

Town Hall,
Birkenhead.
May 22nd, 1929.

E. W. TAME,
Town Clerk.

Metropolitan Asylums Board.

APPOINTMENT OF BACTERIOLOGIST AT THE BOARD'S ANTITOXIN ESTABLISHMENT.

The Board invite applications for the appointment of Bacteriologist at their Antitoxin Establishment, Belmont Laboratories and Stables, Sutton, Surrey.

The candidate appointed will be responsible, under the Director, for the Bacteriological and Serological work of the laboratories. He will be required to make himself acquainted with the general running of the laboratories, and so be in a position to take charge, when required; and also, subject to the approval of the Director, to carry out research in connection with the work of the laboratories.

Candidates must be qualified by law to practise Medicine and Surgery in England, and should possess a sound knowledge of "immunity" and practical acquaintance with immunological methods.

The commencing salary is at the rate of £700 per annum.

Application forms containing full particulars of the appointment may be obtained, by sending stamped addressed foolscap envelope, from the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4, to whom completed applications must be returned not later than 10 a.m. on Wednesday, June 19th.

ALLAN POWELL, Clerk to the Board.

Metropolitan Asylums Board.

INFECTIOUS HOSPITALS SERVICE.

APPOINTMENT OF ASSISTANT MEDICAL OFFICERS.

Applications are invited for appointments as Junior Assistant Medical Officers in the Infectious Hospitals Service.

Candidates must not exceed 30 years of age, and must be duly registered and qualified by law to practise both Medicine and Surgery in England. Junior Assistant Medical Officers are subject to annual re-election.

Salary £500 per annum. Married quarters are not available.

Assistant Medical Officers are required to reside in the Hospitals, and to pay for board, lodging, and washing at the rate fixed from time to time by the Board's Finance Committee. At present the rate is £130 per annum.

Application to be made not later than 10 a.m. on Wednesday, June 19th, on form obtainable by sending stamped addressed foolscap envelope to the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4.

ALLAN POWELL, Clerk to the Board.

City of Birmingham.

FOURTH ASSISTANT MEDICAL OFFICER required at the CITY HOSPITAL FOR INFECTIOUS DISEASES, LITTLE BROMWICH. Previous resident Hospital post essential. The appointment will be made for 12 months only. Duty to commence not later than August 1st.

Salary £300 per annum, together with board, residence, and laundry.

Forms of application may be obtained from the Medical Superintendent, and should be returned to him on or before Saturday, June

Birmingham Union.

SELLY OAK HOSPITAL.

CASUALTY OFFICER (Male).

Applications are invited from fully qualified medical practitioners for the appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children and Infectious sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-therapeutic, Massage, and Sunlight Departments. Over 2,500 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The person appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointment may be obtained from the Medical Superintendent, Mr. R. P. STANLEY KELMAN, M.B., F.R.C.S. (Eng. and Edin.) at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Wednesday, June 12th.

Union Offices,
Edmund Street,
Birmingham.
May 24th, 1929.

C. P. BEECH,
Clerk to the Guardians.

Ministry of Health.

The Minister of Health invites applications from registered medical practitioners (women) for appointment as MEDICAL OFFICER on the staff of the Ministry.

The salary commences at £600 per annum and rises by yearly increments of £25 to £900, and then by yearly increments of £50 to £1,100 per annum. In addition to the salary, a bonus, which varies with the cost of living, is payable; the bonus on the minimum salary is at present £176 7s.

The appointment will be subject to the usual Civil Service conditions as to pension, marriage, holidays, etc.

Candidates must be registered medical practitioners of not less than 7 years' standing and should have had special experience in Obstetrics and of Maternity and Child Welfare work under a Local Authority. Preference will be given to candidates possessing a University Degree in Medicine and a Diploma of Public Health.

Medical Officers are required to devote their whole time to the Public Service and must be prepared to work in any part of England or Wales if required to do so.

Canvassing Members of Parliament or officers of the Ministry will render a candidate liable to disqualification.

Forms of application, with further particulars of the appointment, may be obtained from the Director of Establishments, Ministry of Health, Whitehall, S.W.

No application can be considered unless received on the prescribed form not later than June 25th.

County of London.

The London County Council invite applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (male) in its Mental Hospitals Service. Candidates must be under 35 years of age and be registered to practise both in Medicine and Surgery in England.

Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, the present total commencing remuneration being approximately £423 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly), if required to be resident. Candidates appointed will be pensionable, under the Asylums Officers Superannuation Act, 1909.

Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1.

Completed applications must be received by Friday, June 14th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

Borough of Ilford.

APPOINTMENT OF WOMAN ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from legally qualified medical women for the office of Assistant Medical Officer of Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and General Public Health work. Candidates must possess the Diploma of Public Health or similar qualification, and have had Post-Graduate experience in Maternity work and Children's Diseases.

The commencing salary of the officer will be £450 per annum, rising, on report of satisfactory service, by annual increments of £25 per annum to £500 per annum (no bonus), and with free board and residence at the Corporation's Isolation Hospital.

The person appointed will be required to devote whole time to the duties of the office, to reside at the Isolation Hosital, and to enter into a contract for the due performance and fulfilment of all the duties and conditions governing the appointment.

The appointment is subject to the approval of the Ministry of Health, to satisfactory medical examination, and to the staff regulations for the time being in force.

The appointment is also subject to the Local Government and Other Officers Superannuation Act, 1922.

Candidates must not be more than 45 years of age.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Woman Assistant Medical Officer of Health," must be received at my office, at the Town Hall, Ilford, not later than Tuesday, June 18th.

Canvassing, directly or indirectly, is prohibited and will disqualify.

By Order,
Town Hall,
Ilford.
June 3rd, 1929.

ADAM PARTINGTON,
Town Clerk.

Lancashire County Council.

APPOINTMENT OF ASSISTANT TUBERCULOSIS MEDICAL OFFICER for HIGH CARLEY SANATORIUM, Near ULVERSTON

The Lancashire County Council are prepared to receive applications for the post of Male Assistant Tuberculosis Medical Officer (unmarried) for the High Carley Sanatorium (112 beds). Salary £450, rising by two annual increments of £25 to £500 per annum, together with the following emoluments: board, furnished apartments, fuel, light, and laundry.

Applicants must be registered medical practitioners between 25 and 34 years of age, and the person appointed must devote the whole of his time to the duties as defined by the Council. Candidates must have held House appointments for at least six months in a General Hospital, and have had special experience in the diagnosis and treatment of Tuberculosis.

The possession of a Diploma in Public Health and practical experience in X-ray work will be deemed additional qualifications for the post.

Contributory Superannuation Scheme is in operation, with medical examination for entrants.

Forms of application, terms of appointment, and list of duties can be obtained from the undersigned. Closing date June 12th. All letters must be marked on the outside "Assistant Tuberculosis M.O."

GEORGE ETHERTON,

APPOINTMENTS.—Contd.

Royal Devon & Exeter Hospital,
EXETER. (225 Beds.)

ASSISTANT HOUSE SURGEON (Male).

Applications are invited for the post of Assistant House Surgeon at this Hospital, vacant on July 1st next. The appointment is for six months, but candidates are eligible for re-election.

The duties include assisting in the Ear, Nose, Throat, Radiological, and Casualty Departments, and the giving of anæsthetics.

Salary at the rate of £100 per annum, with board, apartments, and washing.

Applications, giving particulars as to age and qualifications, together with copies of three recent testimonials, should be sent to the undersigned as soon as possible.

By Order of the Committee,
S. S. COLE,
June 4th, 1929. Secretary & Manager.

Warrington Infirmary and
DISPENSARY.

The Board of Management invite applications for the post of HOUSE PHYSICIAN (male, unmarried). Applicants, who must be of British nationality, must be duly qualified medical practitioners.

Salary £150 per annum, with board, apartments, and laundry. The post is tenable for six months, with probable promotion at the end of that time. The vacancy is due to the promotion of the present staff.

The Hospital has special departments—i.e., Orthopædic, Skin, Aural, Genito-Urinary, Gynæcological, etc.

Applications, stating age and qualifications, with copies of three recent testimonials, should be sent in at once to the undersigned.

By Order,
HENRY L. BOOT,
May 18th, 1929. Supt. & Secretary.

Huntingdon County Hospital.

Male HOUSE SURGEON wanted at once. Salary at rate of £125 per annum, and washing. Applications, etc., to Senior Surgeon, County Hospital, Huntingdon.

Sheffield Union Hospital.

MALE RESIDENT ASSISTANT MEDICAL OFFICER.

The Guardians of the Poor of the Sheffield Union invite applications for the appointment of a Male Resident Assistant Medical Officer at the Union Hospital, Firvale, Sheffield. The Hospital is a large separate Institution containing 840 beds, and is equipped in accordance with modern requirements, and facilities are provided for Pathological and Bacteriological work.

The staff at present consists of a Resident Medical Superintendent, a Resident Deputy Medical Superintendent, and five Resident Assistant Medical Officers, a Visiting Physician, a Visiting Surgeon, and a Visiting Radiologist. The Assistant Medical Officer to be appointed will be required to take duty in such parts of the Hospital or at other Institutions under the control of the Board as may be directed.

Applicants must be duly registered under the Medical Acts, and qualified by law to practise Medicine and Surgery in England and Wales.

The appointment will be limited to two years, the salary being at the rate of £250 for the first year, and £300 for the second year, together with residence, rations, and other usual allowances, the salary being subject to the statutory deductions required by the Poor Law Officers Superannuation Act, 1896.

Letters of application, stating age, qualifications, and experience, together with copies of testimonials of recent date as to professional ability and personal character, to be sent to me without delay.

By Order,
LAWRENCE RICHMOND,
Union Offices, West Bar, Clerk to the
Sheffield. Guardians.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

Telc. Address: Triform, Wesdo—London.

12, Stratford Place, Oxford Street, W.1.

Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

NEW ZEALAND.—(North Island).—In an up-to-date Town (pop. 12,000, with a further 10,000 in outlying district) within 12 miles of the sea, a well-established PRACTICE worth last year over £1,000, including appts. averaging £280. Visits 10/6 to 21/-, mileage extra. Fees 5/- to 21/- Midwifery 3 to 10 gns.; about 30 cases yearly. Surgery premises can be rented on lease, and contain consulting room, waiting room, 3 bedrooms. Electric light. Garden. Purchaser can choose his own place of residence. Premium 1½ years' purchase, with or 2 years' partnership introduction as required.
21. PARTNERSHIP.—LONDON.—In a populous district, the half share of an old-established middle and working-class Practice, worth over £2,000 p.a., including panel of 1,300. Visits 3/6 to 10/6. Expenses light, car not necessary. House contains professional accommodation, 2 reception, 2 bedrooms, bathroom, etc. Held on lease at rental of about £60 p.a. Premium 2 years' purchase.
22. SHEFFIELD.—Good-class non-panel non-dispensing PRACTICE in best residential district. Average income for last three years over £3,000. Fees 5/- to 21/- Midwifery 3 to 10 gns.; about 30 cases yearly. Surgery premises can be rented on lease, and contain consulting room, waiting room, 3 bedrooms. Electric light. Garden. Purchaser can choose his own place of residence. Premium 1½ years' purchase, with or 2 years' partnership introduction as required.
23. STAFFS.—LARGE TOWN.—Owing to ill health of present Incumbent, an old-established good-class non-panel non dispensing PRACTICE is for immediate disposal. Commodious house, in best residential road. Price for freehold £1,600, part on mortgage. Premium £1,500, £1,000 down.
24. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
25. BORDERS OF NORFOLK AND SUFFOLK. — Very old-estab. good middle-class PRACTICE, averaging over £1,000 p.a., including panel of 530. Visits from 3/6. Easily worked. Very attractive house, modernized, and containing 3 reception, 6 bedrooms, bathroom (h. and c.), separate professional accommodation. Price for freehold £2,000. Premium £1,500.
26. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE.—Large Hospital Town within 80 miles of London. A well-established connection averaging nearly £1,000 p.a. (last year £1,059). Patients upper and middle-class. Fees 1½ to 15 gns. House in pleasant position, with ample professional accommodation. Rent £60. Premium £1,500, or offer. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital and successor will be appointed.
27. DEATH VACANCY.—NORTH DEVON.—UNOPPOSED COUNTRY PRACTICE in delightful district. Very old-established mixed general Practice held by the late Incumbent for the past 16 years. Income for 1928 £1,266, including panel of approximately 700. Exceptionally good house, standing in 2 acres of garden, with 2 reception, 6 bedrooms, etc., surgery and waiting room. Electric light. Garage for two cars. Premium for Practice and house £4,000.

Full Schedule of Terms and Conditions will be forwarded on application.

COAGULEN-CIBA IN HÆMORRHAGE

Five correspondents in *The British Medical Journal*, July 28th, 1928, p. 182, testify to the value of Coagulen-Ciba in Hæmophilia.

Reports on the successful administration of Coagulen-Ciba were published in *The Lancet*, October 31st, 1925, p. 918, Intestinal Hæmorrhage; *The Lancet*, June 13th, 1925, p. 1238, Hæmoptysis treated by Intrapulmonary Injections; *The Lancet*, January 24th, 1925, p. 176, Hæmorrhage following Tonsillectomy.

Three cases (two Hæmoptysis, one Bowel Hæmorrhage) successfully treated with Coagulen-Ciba by the mouth are reported in the *Journal of the Royal Naval Medical Service*, No. 1, Vol. XII, pp. 64-65.

Full particulars and reports to Physicians on request.

THE CLAYTON ANILINE CO., LTD., Pharmaceutical Department, 40, Southwark Street, LONDON, S.E.1.

SCHACHT'S
Original Preparations
FOR THE USE OF
THE MEDICAL PROFESSION.

LIQ. BISMUTHI "SCHACHT."

Absolutely pure and perfectly stable. The original preparation and the most physiologically active solution of Bismuth. Dose: One drachm, diluted.

PEPSINA LIQUIDA "SCHACHT."

A palatable, standardized solution of gastric juice from the pig. Useful in the treatment of dyspepsia. In ten-minim doses it gives excellent results in infantile diarrhœa. Adult dose: One drachm, diluted.

PEPSINA LIQUIDA C. BISMUTHO "SCHACHT."

Each fluid drachm contains in a concentrated form, besides the Pepsina Liquida, one fluid drachm of Liquor Bismuthi "Schacht." Dose: One drachm, diluted.

PEPSINA LIQUIDA C. BISMUTHO CO. "SCHACHT."

Contains one grain of Soluble Euonymin in each fluid drachm, in addition to the Pepsine and Bismuth. Dose: One drachm, diluted.

BISEDIA.

A combination of Schacht's Liquor Bismuthi and Pepsina Liquida, with Morphia and Hydrocyanic Acid. Of the greatest value in the treatment of Acute Dyspepsia, Gastric Ulceration, Vomiting of Pregnancy, etc. Dose: Half to one drachm, diluted.

LIQ. CASCARÆ DULCIS "SCHACHT."

A palatable and very concentrated aromatic preparation of the finest Cascara Sagrada; free from bitterness and griping action. Dose: Quarter to one drachm.

LENIVA.

An excellent fruit laxative syrup, containing Alexandrian Senna, Figs, Prunes, Tamarinds, etc. Eminently suitable for delicate women and children. Dose: Half to two drachms, according to age.

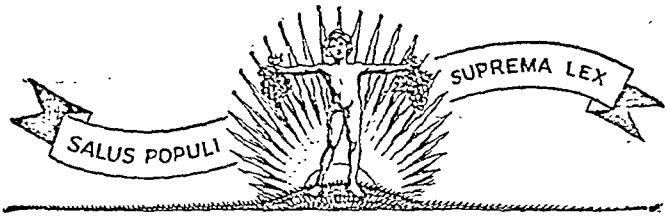
No. 3571. SATURDAY, JUNE 15, 1929. Price 1/3



CONCEALED CONSTIPATION.

Half the constipation in the world is never recognized. So long as some measure of intestinal elimination occurs daily, it is commonly assumed that in this department of physiology all is well. Yet the degree of *concealed* constipation may be pronounced, and the large bowel may never be properly evacuated. A vicious circle is thus set up, and the intestinal musculature becomes diminishingly responsive and progressively atonic.

The functional interrelation of the body's whole eliminatory chain is such that intestinal stagnation causes a general hold-up of the scavenging processes even in the remotest tissues. It is probably thus, rather than through direct absorption of toxins from the intestines, that most of the unpleasant symptoms of constipation—headache, malaise, lassitude, etc.—are produced. It is surprising how promptly and completely these symptoms are cleared up by a regular morning glass of Eno's "Fruit Salt" taken before the early cup of tea.

As is generally known among medical men, Eno's "Fruit Salt" is a carefully blended combination of alkalies with fruit acids, and is absolutely free from such nauseating mineral purgative salts as the sulphates of soda and magnesia. It contains no sugar or added flavouring agents, its palatableness being due to its physical texture and the uniform solubility of its graded particles.

"*The Doctor's Emergency Reminder.*"

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders,"—with or without a bottle of their preparation (Handy or Household size as required). "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the *treatment of poisoning and various other emergency cases.* It is bound in black morocco limp to conform to the style of the previous publications in this series.

J. C. ENO LTD., 160, PICCADILLY, LONDON, W.1

The Standard Hypnotic

Clinical experience over a long period has demonstrated the remarkable value of

'Medinal' in Insomnia

arising from no matter what cause.

The soporific effect is rapid in onset and prolonged in action, and there are absolutely no carry-over effects to be feared.

The ready solubility of 'Medinal' implies quick absorption and rapid elimination.

TABLETS (grs. 5 and 7½). CACHETS (grs. 5 and 10). POWDER. Dose: 5–10 grs. as required.

Clinical specimen and full literature on request from—

The Issue of the BRITISH MEDICAL JOURNAL this week 39,000 copies.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"The book presents a comprehensive account of modern knowledge of cardiology."—BRITISH MEDICAL JOURNAL.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

LEWIS'S PUBLICATIONS

With 26 Plates (including 6 coloured) and other Illustrations, 15 Diagrams, and 31 Charts. Demy 8vo. 30s net; postage 9d.

A TEXT-BOOK OF INFECTIOUS DISEASES

Being the Third Edition of Goodall & Washbourn's MANUAL OF INFECTIOUS DISEASES.

Revised and in large part rewritten by E. W. GOODALL, O.B.E., M.D., B.S.Lond., lately Medical Superintendent and Lecturer on Infectious Diseases and Fever Hospital Administration at the North-Western Hospital of the Metropolitan Asylums Board; Vice-President (formerly President) of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, etc.

"Dr. Goodall's long and intimate acquaintance with infectious diseases makes this volume very acceptable . . . . thoroughly up to date and should make a valuable addition to the library of every medical practitioner."—THE LANCET.

JUST PUBLISHED. With Illustrations. Crown 8vo. 6s. net; post. 5d.

PERCUSSION OF THE CHEST

By J. B. McDOUGALL, M.D.Glasg., F.R.C.P.Ed., F.R.C.P.S.Glasg., Medical Director, British Legion Village, Preston Hall, Aylesford, Kent.

"Percussion is one of the everyday methods of physical diagnosis. It is upon perfection of technique that we must rely for the best results."—EXTRACT FROM INTRODUCTION.

With 25 Illustrations, including 17 Plates. Demy 8vo. 9s. net; postage 5d.

STERILITY IN WOMEN: Diagnosis and Treatment.

MEDICAL ANNUAL, 1929

A YEAR-BOOK OF TREATMENT AND PRACTITIONER'S INDEX. A Review of the World's Progress in Medicine and Surgery, arranged in Alphabetical order for easy Consultation.

"Contains a thoroughgoing survey, valuable alike to the general practitioner, the specialist, and the laboratory worker, of the progress of medicine and the ancillary sciences in Europe and America during the past twelve months."—B.M.J. *"Stands alone in British medical literature."*—LANCET.

Bristol: JOHN WRIGHT & SONS Ltd. [*New Illustrated Catalogue Free.*] London: SIMPKIN MARSHALL Ltd.

METHODS AND USES OF

HYPNOSIS AND SELF-HYPNOSIS.

By Bernard Hollander, M.D. 6s.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as a survey of all that is scientifically known of this form of psychotherapy.

GEO. ALLEN & UNWIN, Museum Street, London, W.C.1.

"Should be in the possession of every medical man."—*Glasgow Medical Journal*

URINARY SURGERY A Handbook for the General Practitioner

By W. K. IRWIN, M.D., F.R.C.S.,

Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

¶ "Clearly written . . . furnishes the practitioner with information of great practical value in his everyday work."—*British Medical Journal.*

SECOND EDITION. Revised and Enlarged. Price 10s. 6d. (postage 6d.).

BAILLIÈRE, TINDALL & COX, 7 & 8, Henrietta St., London, W.C.2.

THE MODERN DANCE OF DEATH

By Dr PEYTON ROUS, of the Rockefeller Institute for Medical Research. The Linacre Lecture, 1929. Crown 8vo. 2s 6d net.

In the time of Thomas Linacre men had a passion—strange it now seems to us—for pictures in which they danced with Death. The vogue of these pictures passed in the sixteenth century, and it is the purpose of the author to discuss whether since Linacre's period the underlying dance of death has also changed—that visible to the student of morbid physiology.

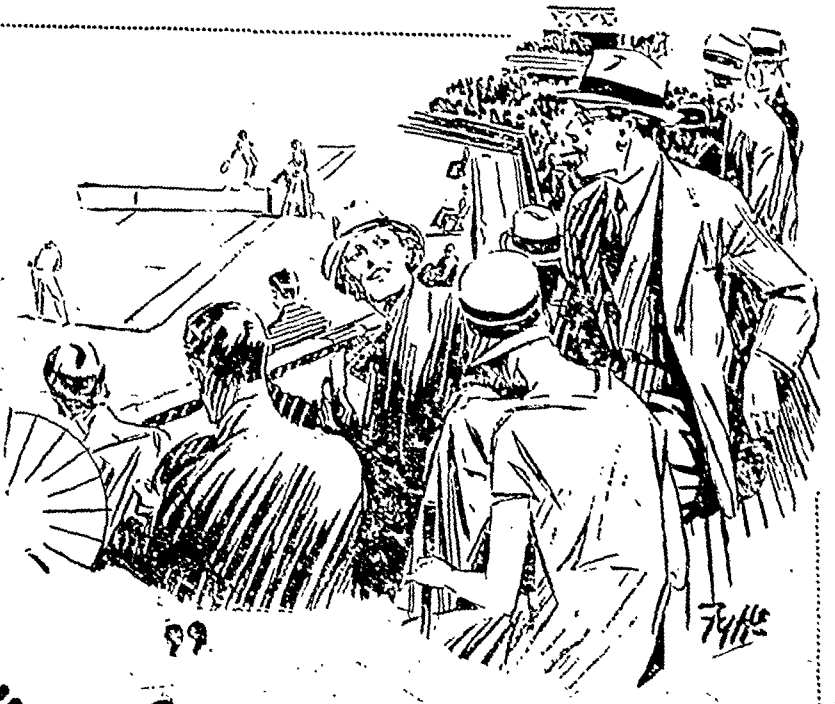
GOOD SERVICE

often depends on a partnership loyally observed. The cloth and the Lining of a suit should be chosen together if the suit is to give full service. Every one of the numerous "COURTINE" LININGS has the name "COURTINE" on the selvedge: there is an undertaking given by the Manufacturers, Courtaulds, Ltd., that hard and constant wear will do no damage. "COURTINE" LININGS provide unrivalled sleekness and richness of quality that renders good dressing a pride and an investment. Ask your tailor to use "COURTINE" LININGS for service and long wear.



"Courtine" (REGISTERED) LINING

The name is on the selvedge.

If any difficulty in obtaining "COURTINE" LININGS, write direct to the Manufacturers: COURTAULDS, LTD., 16, St. Martin's-le-Grand, London, E.C.1

THE £498 CROSSLEY
is a very remarkable car

This 15.7 Coachbuilt Saloon, Standard Model, is a 'luxury-class' car in all respects save one—its price. It is a fine big roomy car, with adjustable front seat and ample accommodation for five. It is beautifully finished—cellulose without, leather upholstery within. Its springing is so perfect that it takes a very bad road indeed to disturb the peace of body of the most susceptible passenger. On steep hills it rejoices to show what its big-hearted engine can do. And its price, including full equipment, is but £498.

See also the 15 7 Coachbuilt De Luxe £575, and the two-litre Sports.

Salt and Son Ltd.

VARICOSE VEINS IN HOT WEATHER.

Wearers of Elastic Hosiery find the ordinary type of Stockings, etc., rather trying during a hot spell.

We now have all grades made in a special weave, which, whilst still retaining all the supporting qualities, by its perforated finish, allows free passage of air to the limb.

These appliances are thereby lighter in weight, cooler in wear, and a great comfort to patients in the Summer Season.

The cost is only fractionally more (owing to the increase in weaving), but it is economy in the truest sense, because the Winter Hose can be returned for necessary cleaning and repairing.

Excessive perspiration, which so quickly shortens the life of elastic goods, is avoided by the use of

SALT'S OPEN-WEAVE ELASTIC HOSIERY.

English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

EXCISION OF LARYNGEAL POLYPI.

Typical Case.

C. H., Female, aged 23 years.

Diagnosis: Laryngeal polypi; tracheotomy.

Operation: Laryngotomy, excision of polypi, laryngectomy.

Anæsthesia: Local infiltration block.

First Operation: Classical infiltration block was made. Larynx was opened in the mid-line in front and a number of polypi removed, using scissors, curette, and cautery. A rubber tube was placed on the larynx and allowed to remain. The incision was closed with drainage. The patient had relief for some time and could even breathe through the normal channels, but within three months the granulation-like masses began to appear once more about the tracheal opening, and laryngectomy was decided upon.

Second Operation: Anæsthesia: A wide infiltration was made, using 90 c.c. of a 0.5 per cent. Novocain-Adrenaline solution. The incision was made and the trachea divided just above the original tracheotomy wound. 10 cm. of the anterior wall of the oesophagus was removed with the larynx. A considerable portion of the thyroid gland was also removed with the mass. The wound was drained extensively, the skin being closed with silkworm sutures. The patient's pulse and colour did not change during the operation. The anæsthesia was ideal. This patient has remained well to date.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

GRATITUDE
to
Humanised Trufood
and
the Doctor who recommended it

The value of Humanised Trufood for difficult cases of infant feeding is indicated by the testimonials we receive from parents, thanking Trufood and the doctor who recommended its use for their baby's progress and development.

A mother of a premature baby writes:

"DEAR SIRS,

"I feel I would like to tell you of the wonderful progress my baby girl has made on your food.

"She was a premature baby (7 months) and weighed nearly 3 lb. The Doctor gave us very little hope for her, and as I could not feed her myself the Doctor ordered Humanised Trufood.

"Even from the first feed she did not throw any back, and it seemed to agree with her wonderfully.

"The Doctor said it was wonderful, and she came on steadily and has not been a bit of trouble.

"Yours faithfully,
(Signed) "G. M—— (Mrs.)."

May we have the pleasure of sending you samples in order that you may submit Humanised Trufood to clinical observation?

HUMANISED
TRUFOOD
Nearest to Mother's Milk.

TRUFOOD LIMITED, THE CREAMERIES, WRENBURY, NR. NANTWICH, CHESHIRE

Valentine's Meat-Juice

In the **Treatment** of **Weak Babies**, in the **Gastric** and **Enteric Troubles** of **Infants** and in the **Wasting** and **Febrile Diseases** of **Children**, the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** has been **Demonstrated** in

Hospitals for Children.

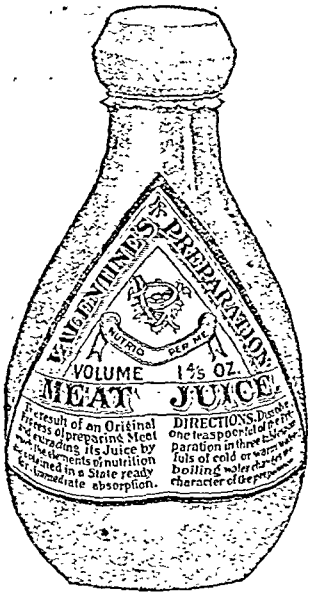
The quickness and power with which **Valentine's Meat-Juice** acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

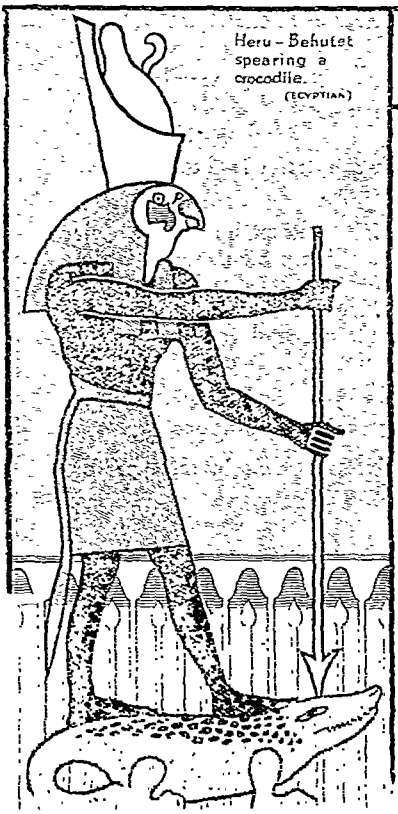
Physicians are invited to send for Clinical Reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

JB 95





OVALTINE

MALNUTRITION IN CHILDREN

Nervous and mentally unstable children are numerous, and their condition, being naturally deep rooted and inherent in the organism (as neuroses and psychoses are not of sudden onset), is difficult to remove.

From its composition and properties physicians recognize that "Ovaltine" is especially well adapted to the feeding of growing children, both in health and sickness. The mere fact that when added to a vitamin-free diet it will almost at once set up in a puny, poorly grown, and malnourished animal a growth and development normal in every respect, should in itself carry conviction.

When, however, the results of our laboratory experiments are amply and widely confirmed by the successful use of "Ovaltine" in clinics, and by prominent pediatrists throughout the world, assuredly it may be said that assurance has become doubly sure. The delicious flavour of "Ovaltine" appeals particularly to children, and they thrive upon this perfectly balanced food in a completely satisfactory way. A pamphlet, well illustrated and dealing at length with the scientific tests referred to above, will be gladly posted on request.

A liberal supply for clinical trial sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W.7.

'Panopepton'

LEAN BEEF—the entire group of nitrogenous substances, those natively soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, with the natural savoury extractives and minerals:

ENTIRE WHEAT GRAIN—the peculiar complex of nitrogenous substances, those naturally soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, the farinaceous substance converted into dextrin and maltose, and with the associated savoury constituents and minerals.

Of the beef nothing is excluded but the indigestible connective tissue and lipoid. Of the wheat nothing is excluded but the insoluble inert cellulose and silica of the shell of the grain.

'Panopepton' is of a uniform standardized composition; it is highly agreeable; requires no preparation. It is a potent restorative and emergency food in serious straits; a fortunate recourse for the invalid.

Supplied in 12-oz. bottles.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),

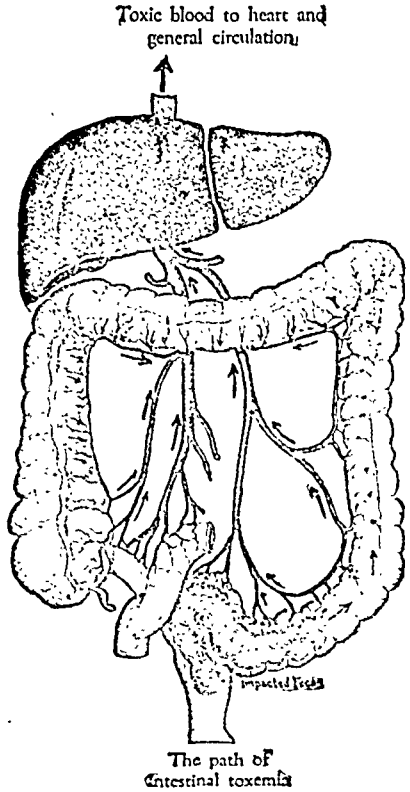
Dissolves Intestinal Toxins



The path of Intestinal toxemia

Not the least valuable of its properties is the behaviour of Nujol toward intestinal toxins.

If a watery solution of indol be shaken up with Nujol, more than half the indol is quickly taken up. Nujol readily dissolves this and other waste and poisonous substances, many of which are more soluble in Nujol than in water. Once absorbed in Nujol they cannot be absorbed by the system, as Nujol itself is non-absorbable.

The brownish colour of Nujol as seen in the stool is partly due to toxins which it holds in solution.

Nujol is a safe and effective treatment in all types of constipation and intestinal toxemia.

BRAND'S ESSENCE OF BEEF for INVALIDS

has enjoyed the confidence of the medical profession for over 90 years. A nourishing stimulant that demands the least amount of energy in the process of assimilation and increases the means of defence by raising the powers of resistance.

Mark it in your memo book

Brand's Essences are scientifically prepared, in jelly form, from the finest English meats, and contain upwards of eleven per cent. of proteid. The nourishing and stimulating properties are IMMEDIATELY ABSORBED, without residue, in the alimentary canal. No time is lost in process of assimilation. No work entailed by the digestive organs. Absolutely pure. Contains no gelatine, colouring, or preservatives. Good for young and old alike.

BRAND'S ESSENCE OF CHICKEN contains the same nourishing and stimulating properties as Brand's Essence of Beef, and for over 90 years has been recommended by the medical profession when required by prevailing conditions.

A R C

Indicated in the treatment of

all the gonadal dysfunctions of men and women

Sex gland deficiencies in men and women are successfully treated with Ovacoids, Testacoids and Ampacoids.

Each
OVACOID contains:—
Autacoids representing Fresh Ovary ... ... 5 grs.
Autacoids representing Fresh Anterior Pituitary ... ½-gr.
Indications:—Sex gland deficiencies in the female, such as Amenorrhœa, Dysmenorrhœa, Menorrhagia, Sterility, Chlorosis, Frigidity, Sexual Neurasthenia, Hypertension and Functional or Artificial Menopause. Bottles of 50 Tablets.

AMPACOIDS
Ampacoids aqueous solutions for hypodermatic injection of the autacoids of Ovary, Testicle, and Prostate respectively.
They are physiologically standardized, and are free from all the contaminating substances present in ordinary gland extracts. Boxes of 6 1 c.c. Ampoules.

Samples and Literature from Sole Agents for United Kingdom and Irish Free State:—Coates & Cooper, 41, Great Tower Street, E.C.3.

Each
TESTACOID contains:—
Autacoids representing Fresh Testicle ... ... 25 grs.
Autacoids representing Fresh Prostate ... ... 5 grs.
Indications:—Sex gland deficiencies in the male, such as Sexual Neurasthenia, Premature Senility, Diminished Potency, the Male Climacteric, and whenever Sexual Stimulation is sought. Bottles of 50 tablets.

Disturbances of Menstruation and the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases.

The chemical composition of Kalzana, calcium - sodium - lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is supplied in a convenient tablet form, is free from harmful by-effects and is pleasantly flavoured.

Dispensed by Chemists in air-tight packets containing 50 and 100 Tablets.

Kalzana

Exactitude in preparing Milk Mixtures

very often solves the most difficult problems set by the artificially-fed infant. Careful dilution of cow's milk will give the correct percentage of casein, and the addition of Albulactin provides exactly the proportion needed to meet the digestive capacity of the infant. Albulactin is pure soluble lactalbumin—the vital proteid of milk—upon which depends the formation of a fine, flocculent curd in the infantile stomach. Albulactin simplifies the preparation of milk mixtures for all infants, from the premature weakling to the normal healthy baby.

"The British Medical Journal" says:

"A modified milk, prepared by mixing cow's milk, albulactin, and water in such proportions that the casein and albulactin were in approximately equal amounts, formed much less curd when acidified than diluted cow's milk, containing the same proportion of total protein. There appears to be every reason to expect this preparation to be of great value in the hand feeding of infants."

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO., Amsterdam, Holland.

RHEUMATOID ARTHRITIS

Guesses and Gaps in its Ætiology

"The whole story of proteid metabolism consists, at present, mostly of guesses and gaps."—Sir MICHAEL FOSTER.

WHY do thousands of people suffer from various forms of rheumatism, yet tens of thousands escape when living under precisely similar conditions of climate, diet, etc.?

The answer can be found in two sound premises: there is present (1) Pre-existent susceptibility in joints and fibrous tissues to invasion by micro-organisms or toxins; (2) Diminished resistance of these tissues to such invasion.

Bacillary Toxæmia has to be fought throughout the entire gastro-intestinal tract, but it is developed out of all bounds in the colon of man: in that vast nursery more obscure metabolism takes place than can ever be completely investigated.

Laxatives and purgatives relieve a loaded colon, but they have no action upon the intestinal organisms whose toxins are so virulent: *these remain, after the contents have been removed by purgative action, to set up the same disturbance with the next meal.*

It would seem good practice, therefore, to destroy as effectively as we can the pathogenic bacteria of the colon in all forms of rheumatic diathesis, with an efficient, non-toxic bactericide. Such a product is now readily available in the form of Dimol, which for over eight years has been giving most gratifying results in the treatment of putrefactive and other bacterial invasions of the intestinal tract.

Literature and samples may be obtained from the

The Treatment of

Puerperal Septicæmia

In a recent paper (*B.M.J.*, June 1st, 1929, p. 984) there is published a report showing that puerperal septicæmia, with haemolytic streptococci, responds in a most remarkable manner to therapeutic doses of

RADIOSTOLEUM

Every case under treatment made a complete recovery

This discovery is naturally of vital importance in obstetrics; indeed, the results indicate that its application in practice is likely to prove a most effective means of reducing substantially the maternal mortality rate.

It would appear that the natural sequence of the discovery is that Radiostoleum therapy will be found of inestimable value, throughout the pre-natal period, in building up a reserve of power to resist the onslaught of infection at the critical period.

Radiostoleum is a liquid which is issued in capsules and in bottles of varying sizes. It is administered

(1) in prophylactic doses—as capsules

(2) in massive therapeutic doses—by the teaspoonful

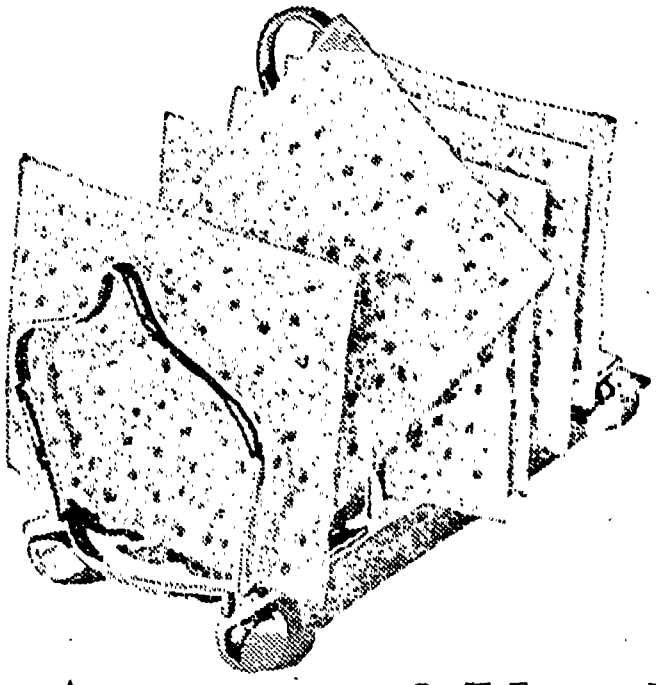
Vit. Pr. 75.



Health Aspects of Vita-Weat

In cases of diet regime a readily acceptable and beneficial alternative to ordinary bread will be found in Vita-Weat—the whole-wheat British crispbread.

The "Lancet's" Report.

Being made from 100% stone-ground whole wheat, Vita-Weat preserves all the vitamins intact. The *Lancet* reports that Vita-Weat is "a valuable foodstuff, more particularly in respect of its content of Vitamin B." Vita-Weat is also rich in Vitamins A and D, in proteins, and in the valuable mineral salts so necessary to health.

Extremely Palatable.

Vita-Weat is extremely palatable, possessing a delicious "crunchiness" and ripe-corn flavour. Its crispness encourages mastication and so promotes a healthy condition of the teeth and gums.

High Calorie Value.

"The calorie value of Vita-Weat," says the *Practitioner*, "is 2,132 per lb., which may be compared with the calorie value of fresh white bread, namely 1,210 per lb." It will thus be seen that Vita-Weat possesses a high physiological fuel value.

To Counteract Constipation.

The branny scales of Vita-Weat act as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

To Prevent Obesity.

The starch granules in Vita-Weat are thoroughly disintegrated. No starch passes unconverted into the body to cause obesity and indigestion. Vita-Weat is "completely assimilable," states a report of the Royal Institute of Public Health.

Peek Frean's

Vita-Weat

PEEK FREAN & CO., LTD., DRUMMOND ROAD, S.E.16

ACHLORHYDRIA IN INFANCY

BABIES suffering from gastro-enteritis, measles, pneumonia, or any severe infection, cannot secrete a gastric juice of sufficient acidity to digest their food. The difficulty of "feeding up" during convalescence is due to this deficiency of acid. These infants have an intolerant digestive tract, but need a considerable amount of food in an easily assimilable form. By acidifying the milk with lactic acid, the buffer substances in the milk are neutralised, and the acid of the gastric juice liberated for peptic digestion.

The manufacturers of COW & GATE have surmounted the great difficulties of preparing lactic acid milk, and are offering to the medical profession two grades of dried milk, each containing one drachm of Lactic acid B.P. to one pint of milk.

LACIDAC

HALF CREAM LACIDAC

Contains 16% Fat.

SEPARATED LACIDAC

Contains 1% Fat.

Lactic acid milk has been employed both in infective disorders and in marasmus with great success. Using Lactic acid milk, one institution has reduced the mortality of marasmic infants from 78% to 26%.

The manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods.

COW & GATE Ltd.,

GUILDFORD SURREY

In view of the increasing use of Monsol in clinical practice both in this country and overseas, the following list of standard dilutions has been prepared for the assistance of the Medical Profession:

As an ordinary antiseptic Dressing:—	*1 teaspoonful Monsol to 1¼ pints water (1-200).*
Vaginal Douches and Irrigations:—	*1 teaspoonful Monsol to 3 pints water, gradually increasing to 2 teaspoonfuls Monsol to 3 pints water (1-500 to 1-250).*
Tampons:—	*1 to 2 tablespoonfuls Monsol to ½ pint water (1-20 to 1-10).*
Aerial Spray:—	*1 teaspoonful Monsol to ½ pint water (1-80).*
Packings:—	*1 tablespoonful Monsol to ½ pint water (1-20).*
Instruments, etc.:—	*1 tablespoonful Monsol to ½ pint water (1-20).*
Irrigation & Dressing of Septic Wounds:—	*1 tablespoonful Monsol to 1¼ pints water (1-50).*
In the Sick Room:—	*In all water for washing, for cleaning bedroom vessels, etc., 1 tablespoonful Monsol to 2 quarts of water (1-160).*
Nasal Spray, or Throat Gargle or Mouth Wash:—	*6 to 8 drops Monsol in ½ tumbler of water (about 1-800).*
Cuts, Abrasions, Sores, Stings, etc.:—	*1 teaspoonful Monsol to 1 pint (1-160).*
Midwifery Cases:—	*1 teaspoonful Monsol to 1 pint (1-160).*
In the Bath:—	*1 teaspoonful to a bath full of water.*
Rectal Douching:—	*1 teaspoonful Monsol to 1 pint (1-160).*

Copies of this table may be had by members of the Medical Profession on application to:

ROCK-CUT SHRINE: ONE OF THE FIRST STONE STRUCTURES IN INDIA.—The Indo-Aryans had a long tradition of building behind them when they first began to work in stone; so far as possible they employed the inherited designs that they had used when working in wood. The shrine here reproduced is excavated in the solid gneiss rock and consists of two chambers, an inner circular one, about 20 ft. in diameter, with a domed roof, and an outer one, about 33 ft. long by 20 ft. wide. The walls are 6 ft. 9 in. in height, rising 5 ft. 6 in. higher to the vaulted roof. The walls of the rectangular apartment are carefully chiselled and brilliantly polished, but that of the circular chamber is unfinished. The ornamental façade is a replica of a prototype in timber work, both in general design and in detail, the stone being carved to imitate roofing beams and lattice work.

A British Medical Association Lecture
ON
RHEUMATISM IN CHILDREN.

DELIVERED BEFORE THE DUNDEE BRANCH,
FEBRUARY 5TH, 1929,

BY

GEO. A. ALLAN, M.D., F.R.F.P.S., M.R.C.P.,
VISITING PHYSICIAN AND LECTURER IN CLINICAL MEDICINE, WESTERN INFIRMARY, GLASGOW.

THE reawakening of interest in the subject of rheumatism has been a striking feature of medical history in this country during the past five years. The investigations that had previously been undertaken with characteristic vigour by the American Heart Association were no doubt a factor in the process, but since 1923, when Poynton (who has been an enthusiastic worker on this subject for over a quarter of a century) published a plea for the prevention of rheumatic heart disease, this matter has been constantly before the profession.

The special committee of the British Medical Association appointed to inquire into this subject can also claim some credit for the renewed interest, and in its published reports has helped not a little to clarify the situation and to point the way to further methods of advance. The chief medical officer of the Board of Education in England has repeatedly emphasized the importance of the subject in his annual reports. The Medical Research Council, the Section of Diseases of Children of the British Medical Association, the Society of Medical Officers of Health, the Child Welfare Section of the Sanitary Institute Congress, and the Society of School Medical Officers of Scotland, in addition to numerous Divisions and Branches of the British Medical Association, have all had the matter under discussion. The experiments in after-care carried out by the Invalid Children's Aid Association in their heart homes, and by others in different parts of the country, notably in Birmingham, have demonstrated what can be done in the direction of limiting the devastation of this serious disease.

When one looks up the subject of acute rheumatism or rheumatic fever in some of the older books, description is found of an affection of the joints, which are red, swollen, and painful, exquisitely tender so that even a touch on the bed is feared, usually associated with fever, sweating, and malaise, and with, as a possible complication, heart disease. The description when applied to the adult may be correct, but when transferred to the child is apt to leave a very erroneous impression. The more the disease is studied in the child, the more it is realized that rheumatism is a general infection, of which after all the joint condition is in essence a minor manifestation. The latter is eminently curable, leaves no deformity, and were the disease so limited one would not be so much concerned with its high incidence among the population of this country. In the child the joints seldom occupy the prominent place that they do in the picture of the adult disease, while the heart less rarely escapes from the effect of the general infection.

There may be different explanations offered as to the special susceptibility of the heart in the child, but comparatively recent investigations by Gross and his collaborators in America into the vascularity of the heart afford a possible clue to the problem. It is now generally accepted that rheumatism in the heart is brought to it by the coronary circulation, and not by the blood passing through its cavities. In the child, and for a variable period in adult life, there is a blood supply which can be demonstrated right into the cusps of the various valves. This vascularity tends to disappear first from the arterial valves, and later from the auriculo-ventricular valves, the last cusp to lose its blood supply being the aortic cusp of the mitral valve. It is very suggestive in this connexion that the mitral valve is more frequently involved than the aortic valve, and the cusp more severely damaged as a rule over a series of cases will be found to be the aortic cusp of the mitral. Another point that must be clearly realized at the outset is that rheumatism in its first attack is essentially a disease of childhood. The highest peak of incidence varies slightly, according to different observers, from the seventh to the tenth year of life, the vast majority of primary attacks of rheumatism taking place before the age of 15. When once rheumatism has affected the heart, particularly the valves, it is found that vessels persist in the valves for a much longer period than in healthy hearts, so that in hearts once damaged, even to a slight extent, subsequent attacks of rheumatism are more prone to produce further damage, even in adult life, than in patients who had not had an attack in childhood. If any good, therefore, is to be done towards lessening the prevalence of heart disease, steps must be taken to circumvent the infection in the child. If, with our present knowledge, it is impossible to prevent rheumatism by the study of the disease in the child, it may still be possible to prevent relapses and to lessen the number of cardiac cripples. The aim of anyone interested in this subject must therefore be (1) to determine as far as possible the conditions which produce or predispose to the infection, and (2) to acquire a knowledge of the earliest manifestations which may indicate the presence of the disease. With our present knowledge of the natural history of rheumatism this may be an ideal difficult to attain; this should not hinder the attempt but rather stimulate to further effort.

PREDISPOSING OR EXCITING FACTORS.

Much uncertainty still exists as to the factors which predispose to rheumatic infection. In inquiring into the family history of cases of children suffering from rheumatism, a history is obtained of parents, brothers, or sisters who have been similarly affected in about as great a proportion as is found in the case of tuberculosis, so that the question of heredity in some degree cannot be lightly dismissed. Many believe, and with considerable ground for their opinion, that some children are born with a special liability to acquire rheumatic infection. That children have been born actually suffering from rheumatic endocarditis has been demonstrated, though so rarely as to be hardly worthy of serious consideration in this connexion. Some have gone so far as to suggest that alteration in the balance between the various ductless glands, notably the thyroids, adrenals, and pituitary, has been the basis of the tendency which has been inherited; and there is certainly in many rheumatic children a nervousness and a tendency to tachycardia that make one hesitate before dismissing lightly such a possibility. Such questions, however, have comparatively little practical application, except in so far as helping one generation may be a means of lessening the incidence of rheumatism in the next.

No one, I think, doubts that environment plays an important part in the incidence of this disease, and while statistical evidence as regards dampness is rather contradictory, the spot maps of certain towns in England where a careful inquiry into this question has been carried out are very difficult to explain on any other basis than that dampness in dwellings is a potent factor in predisposing to the disease. Poynton is confident that the rheumatic child fares badly in such surroundings, and that there is a tendency for the rheumatism in such circumstances to become intractable. He states, "I have seen too many examples to be disturbed by any statistics on this point." In addition to the dampness of dwellings, dampness of clothing and footwear should also be considered. These certainly have a direct influence in promoting catarrhal affections, particularly of the nasopharynx. Further, social status apparently plays a part, though the exact factor therein is not obvious. The elementary council or board school provides a much greater percentage of cases than the average boarding or private school.

Sources of Infection.

With regard to the actual infection, little more need be said than that the disease seems undoubtedly to be due to infection of some kind, but that there is still no uniformity of opinion as to whether the micrococcus of Poynton and Payne, or some other organism or symbiosis of organisms, is the exciting factor. Apart from knowledge of the actual

organism, attempts have been made to determine its site of entry into the body, and the one which gains most support is the tonsil. The teeth have also come under suspicion, but with less ground, while some believe that the intestine may harbour the organism after its entry. The results of enucleation of the tonsils have been more or less unsatisfactory. Some of the latest investigations along this line show that relapses are as frequent in the operated as in the non-operated cases. Miller's figures, however, seem to show that removal of the tonsils lessens the liability to rheumatic joint relapses, and that patients who do relapse afterwards usually manifest the infection in the form of chorea. That enucleation of the tonsils is not a preventive against relapses cannot, of course, be used as an argument against their being the site of primary infection, because it is well recognized that once the infection gains entry to internal organs its eradication is a much more difficult problem.

While the last word has not been written on any of these factors, experiments have been carried out over a sufficiently long period, both in this country and in America, to warrant the view that improvement in environmental conditions can affect for the better the prospects of the rheumatic subject.

EARLY MANIFESTATIONS.

Cardiac Rheumatism.

Apart from the comparatively few cases of congenital heart disease, there is no common affection of the heart in childhood except rheumatism, and it should be recognized that the heart may be the first part to show signs of the infection. Mitral stenosis is usually accepted as a typically rheumatic manifestation, and yet in a series of hospital cases with this lesion over a period of ten years 25 per cent. of the males and 31 per cent. of the females gave no history of antecedent rheumatic manifestation. In many of these cases the heart had been quietly damaged without other sign of the disease, for all patients could not have forgotten other symptoms of rheumatism.

We frequently speak of endocarditis, or of pericarditis, but it may be accepted that in neither case does the myocardium escape. The effect which should be sought in this connexion is enlargement of the heart as made out by percussion. We are too apt to ascribe all changes in the size of the heart to pressure effect, but the dilatation is really more dependent on the extent of muscle damage than on the degree of valvular lesion. Likewise in pericarditis with effusion the increase in dullness, which is often ascribed to the fluid, is in many cases due chiefly to the dilated heart. Dilatation of the heart in a child subject to even suspicious rheumatic manifestations would warrant the assumption that the heart was already in the grip of the rheumatic poison. Dilatation of the heart is really the most reliable early sign in a child, as characteristic lesions which would allow one to diagnose valvular involvement, such as mitral stenosis or even aortic incompetence, do not necessarily present themselves early in the disease. Mitral stenosis particularly may take some years before it develops characteristic physical signs. The presence of a systolic murmur at the apex is perhaps one of the most difficult to assess. In the absence of any dilatation of the heart it can usually be neglected if it is the only sign, but in association with dilatation of the heart it is presumptive evidence that the mitral valve is also affected. An aortic systolic murmur is much less common as an early indication of heart involvement, and is rarely present without a diastolic murmur of aortic incompetence as well. The heart rate, in the absence of auriculo-ventricular block, is usually accelerated, but taken as a solitary sign is not of much value in determining implication of the heart, as so many other causes in the young child can produce the same increased frequency. This sign, however, cannot be neglected, and in the absence of any other cause for acceleration, should be reckoned a suspicious feature. Disorder of rhythm in the child is not common. Auricular fibrillation is rare under 15 years of age; heart-block, however, may occur during the acute stage and may be a transient feature. The presence of extra-systoles, generally infrequent in childhood, would suggest some toxaemia.

Mackenzie indicated that the respiratory type of sinus irregularity could be considered as a sign that the heart had escaped. This view is not now generally accepted. Sinus irregularity is not common with a rapid heart action, and consequently its reappearance may be expected if the heart rate becomes slow. This is probably its only significance, as it has been found in association with such a definite muscle lesion as heart-block.

I have purposely placed cardiac rheumatism first on the list, not only on account of its very great intrinsic importance, but because in the child the heart very rarely completely escapes, and also to emphasize the fact that it may be the first part to show signs of the disease.

According to a recently published statistical inquiry covering 500 children in a New York cardiac clinic, the heart was the first part to be affected in 6 per cent. of the patients. Furthermore, some figures which have recently come to light in connexion with disordered action of the heart—irritable heart—suggest that rheumatic infection may lead to this condition in the absence of valvular disease. Thus Parkinson found disordered action of the heart in a higher percentage of cases in men with a rheumatic history without valvular disease than in those with no rheumatic history.

Any of the above signs have a much greater significance when found in association with other typical rheumatic manifestations, and we may now proceed to consider some of these.

Polyarthritis.

Articular rheumatism is the commonest condition, or at least the commonest to be recognized, antecedent to cardiac infection. In the New York series it occurred in 66 per cent. and was the earliest manifestation in 40 per cent. In many cases, of course, there were relapses from one to five times. The diagnosis of these cases presents little difficulty.

Growing Pains.

This is the group to which I would like specially to direct attention. That it is in most cases in the nature of a true rheumatic manifestation seems undoubted. In the New York series it occurred in 67 per cent. of the cases and was the first manifestation in 27 per cent., It should be noted that in 10 per cent. carditis followed without any other polyarthritis or chorea. Until growing pains are considered as worthy of medical treatment, both by the doctor and the parent, many cases will be allowed to drift into the state of cardiac cripples.

Tonsillitis.

It is difficult to present valuable figures for this condition in its relation to heart disease. That tonsillitis is a frequent accompaniment of other definite rheumatic features, that diseased tonsils are more frequent in rheumatic than in other subjects, and that attacks of tonsillitis often accompany or usher in relapses, is undoubted. It was the first manifestation in 14 per cent. of the New York series. Unfortunately the removal of tonsils may also be immediately followed by rheumatic symptoms.

Chorea.

Apart from the chorea which was a feature of lethargic encephalitis at one period of the epidemic, chorea must be considered as rheumatic in origin. It may be the only rheumatic precursor of carditis, and was so in 21 per cent. of the New York series, in which it occurred in 43 per cent. of the cases. It is as frequently followed by severe carditis as is polyarthritis, and its early recognition is important. The fidgety, restless, nervous child requires very special care at school, and it would be an interesting study to determine how much the strain of school examinations is a determining factor in the production of chorea in susceptible children.

Nodules and Other Signs.

I place great stress on the presence of nodules as an aid to diagnosis and treatment. Figures are unreliable, as the nodules must be looked for regularly if their frequency

is to be recognized. Sometimes transient, coming in crops, they are neither painful nor tender, and so may be overlooked. They have a structure similar to that of the submiliary nodules in the heart.

Anaemia, pleurisy, and pyrexia of unknown origin, while also suggestive of tuberculosis, may be early evidence of rheumatic infection.

Clinical Syndromes.

Generally speaking, cases of rheumatic heart disease may be grouped along certain broad lines, as suggested by Poynton. Perhaps the commonest group is associated with polyarthritis, tonsillitis, or growing pains. The second group is that associated with chorea, with or without some of the other manifestations. In either of those the heart may be quietly damaged, and the full effect of the lesion may only be manifest after one or more relapses. In another group, more often also associated with polyarthritis, the heart is the seat of pancarditis, the endocardium, myocardium, and pericardium being involved, and the patient may be very seriously ill from the onset. In still another group without other rheumatic manifestations the heart may be quietly damaged.

Relapse.

This is a well-known feature, and as succeeding attacks rarely fail to increase the cardiac damage, attention to them, or, if possible, their prevention, may do much to lessen the cardiac effects. In the New York series 70 to 85 per cent. of the patients relapsed, the largest figure being found in those in whom the initial attack occurred in very early life. The relapse may be within a year, or delayed for several years. In half the cases in this series the first relapse occurred within one year; in two-thirds within two years; in four-fifths within three years, and in the remainder up to ten years. The susceptibility to infection decreased after the age of 12.

Treatment and Supervision.

In treatment of the rheumatic infection in childhood time and patience are all-important factors, and it is to inability to secure these from all the parties concerned that many of the failures must be ascribed.

The salicylates, while potent in relieving symptoms and fever in joint cases, seem to fail when the heart or brain is involved. Not only so, but some would argue that the rapid amelioration of symptoms in joint cases induces a false sense of security, so that sufficient time is not allowed for the heart to recover its tone. When the heart is actually the seat of infection salicylates seem to be of little value, and relapses of fever are about as frequent with salicylates as without them.

Rest in bed should be demanded till all signs of activity have passed, and for some time thereafter. Fever and pain are definite and easily appreciated indications for rest, but, in their absence, nodules or tachycardia are equally significant. When it is decided to allow the patient to get up the heart rate should be carefully watched, and any undue acceleration accepted as an indication for more rest. Later, gradually increasing exercise, with the same precaution, is of value. Iron and cod-liver oil help to restore vigour to the cardiac muscle, and should be continued for some time. Experience shows that for many of the cases prolonged convalescence, under good hygienic conditions, with fresh air and sunshine, is necessary.

The problem with which we are faced in trying to deal with rheumatic heart disease hinges on the difficulty of securing lengthy treatment. The public (medical and lay) have been educated to face prolonged treatment in tuberculosis, but not yet in rheumatism. Heart disease kills annually as many as tuberculosis, and, like it, the rheumatic type kills early. Looked at as an economic problem rheumatism deserves as much consideration as tuberculosis, but, of course, the question of isolation does not arise in the same way, and so a good argument is lost.

For the well-to-do the doctor and parents can, if alive to the need, secure the necessary treatment; but rheumatic heart disease is more common in a grade of society that cannot readily face such a course. The hospitals obviously cannot at present provide beds for the lengthy residence that is very often required. The hospital convalescent homes are suitable neither in size nor arrangement to deal with those cases. The British Medical Association subcommittee put forward a plea for the establishment of special residential hospital schools or homes, and the Medical Research Council, in no uncertain words, argues on similar lines: "The plain need for organized after-care offers an urgent but soluble problem of preventive medicine, too long neglected, and every motive of humanity and wise economy should impel the community to provide the after-care as rapidly as possible."

All cases, of course, are not suitable for such homes—for instance, advanced or acute cases. But there are the children who have just passed through an attack of arthritis, chorea, or carditis, or very mild or even potential cases, or quiescent cases, for whom the strain of ordinary school life is too great. The Birmingham people, as a result of the earlier years' working, have had the accommodation doubled, and all reports are favourable as to the value to the patients. Until such places are available, and even afterwards, much remains to be done. All rheumatic children need special and regular supervision, and it seems to me that only by co-operation between practitioners, ante-natal clinic workers, school medical officers, and hospitals, will this be efficient, as first manifestations may be observed by any one of them.

The Rheumatism Clinic.

My own feeling is that any scheme on the lines adopted at Paddington Green under Dr. Reginald Miller serves a useful purpose. Attached to the hospital is a supervisory centre where all known rheumatic children are asked to attend. A temporary scheme of notification is adopted so that the medical officer of health can also give his help. Patients attending are carefully recorded and registered. Any line of treatment considered necessary is recommended only, and is carried out by the family doctor or the hospital, as is considered best. Children who would benefit by country residence are recommended to the care of the Invalid Children's Aid Association.

Another very useful function of such a centre is that of education. The parents are provided with a card giving general instructions on the care of rheumatic children. Similar instructions have been given in other parts of the country through the school medical officers whenever a case presented itself at the routine examination. Education of school nurses and teachers has also an important place in any scheme, as these can often detect early cases of chorea or other features of ill health before the doctor is called in.

The essential feature of any such scheme is that there must be co-operation between the various bodies concerned. No patient should be dismissed from hospital without information being sent to the practitioner or rheumatic centre, and, if fit for school, to the school medical officer. Similarly, cases seen at school should be notified to the practitioner or centre for supervision, while there should be ready access to hospital for patients requiring special care. The function of the centre would naturally be that of co-ordinating and supervising.

To make any impression on the incidence of rheumatic heart disease the problem must be faced from the aspect of rheumatism in childhood. At that stage alone is there any hope. The treatment of auricular fibrillation is often an eminently satisfactory piece of work, but, after all, it is only a patched-up job. To prevent relapses in a child, or, better still, to prevent rheumatism, is to save lives.

Even without a complete knowledge of all the facts of the natural history of this disease much good can be done now by: (1) Education of all in touch with child life—parents, teachers, nurses, doctors—in the early manifestations, the best plan to combat them, and the risk of neglect. (2) Prolonged care, by the doctor, of the child who has been attacked until all signs of activity have ceased. (3) Prolonged after-care in suitable surroundings for those who are recovering. (4) Constant supervision to detect the early signs of ill health, or of relapses.

THE INFLUENZA EPIDEMIC OF 1918:

COLOUR OF THE BLOOD IN FATAL CASES.

BY

J. S. HALDANE, C.H., M.D., F.R.S.

ONE of the most striking facts about the world-wide and extraordinarily fatal epidemic of "influenza" in 1918 was that in the bad cases one of the symptoms was a peculiar blue or violet form of cyanosis. At the time this cyanosis was attributed to broncho-pneumonia; but against this explanation was the fact that administration of oxygen failed to abolish or diminish the cyanosis, whereas in the cyanosis which sometimes accompanies ordinary lobar pneumonia, or the lung inflammation of poisoning by irritant gas, the cyanosis can usually be abolished easily by adding some oxygen to the inspired air.

In a paper published in the *British Medical Journal* of August 1st, 1925 (p. 187), on the presence post mortem of nitric-oxide-haemoglobin, by Dr. Banham, Dr. Savage, and myself, a fatal case of broncho-pneumonia (mistaken at first for carbon monoxide poisoning) was described, in which the blood was found to be everywhere red post mortem, and to give certain of the usual tests for CO-haemoglobin, although the patient was cyanosed just before death, and had not been exposed to carbon monoxide at all. The red colour was evidently due to NO-haemoglobin, which appears post mortem in poisoning by nitrite,[1] while the cyanosis during life was due to the fact that in poisoning by nitrite methaemoglobin is formed, producing practically the same colour in the blood as ordinary cyanosis due to reduced haemoglobin.

In this paper we mentioned the fact that Dr. Banham, when in command of the medical section of the military hospital at Cannock Chase during the war, had repeatedly observed that in the bodies of those who died in the 1918 influenza epidemic the blood was red on exposure post mortem. He had also made a special report on the subject to the War Office.

Since our paper was written I have received information from the doctors and nurses who saw the bodies in fatal cases, both in this country and in France; and they confirm Dr. Banham's experience that the blood was red post mortem, though cyanosis was present during life.

It thus appears to be at least extremely probable that the organism responsible for the very fatal character of the 1918 epidemic was a nitrite-forming organism, and that the main immediate cause of death was anoxaemia due to conversion of oxyhaemoglobin into methaemoglobin. In fatal nitrite poisoning in animals the immediate cause of death is anoxaemia.

Although nitrite-forming organisms are familiar to soil microbiologists, very little, if any, attention has hitherto been given to pathogenic organisms of a similar character. Apart from the 1918 influenza epidemic I have heard of several fatal cases of broncho-pneumonia in which deep cyanosis, probably due to methaemoglobin, was present. It is probable, therefore, that such cases are not very rare, even in the absence of an epidemic of them.

I have written this paper in the hope that some case of this kind may be diagnosed clinically or post mortem, and a proper bacteriological investigation made. It is easy to detect methaemoglobin clinically in a drop of blood, and equally easy to recognize nitric-oxide-haemoglobin post mortem. It seems, however, that unless there is any suspicion of carbon monoxide poisoning not much attention is usually paid at post-mortem examinations to the colour of the blood.

TREATMENT OF PRURITUS ANI AND ANAL FISSURE:

THE USE OF ANAESTHETIC SOLUTIONS IN OIL.

BY

W. B. GABRIEL, M.S.,

SENIOR ASSISTANT SURGEON, ST. MARK'S HOSPITAL.

FROM a practical point of view cases of pruritus ani may be divided into two main groups:

1. The group in which some definite local cause is present. This is usually some lesion which causes an abnormal amount of perianal moisture; amongst the commoner of these may be mentioned prolapsing piles, external piles, fissure, fistula, hypertrophied papillae, rectal polypi and tumours, threadworms, proctitis, etc. Treatment of cases in this group, if limited to removing the exciting cause, together with treatment of the perianal region with simple lotions and powders, is usually effective.

2. The second group is that in which patients complain of persistent severe itching, but examination reveals none of the obvious causes enumerated above. The rectum is smooth, and examination, as a rule, is negative, except that some evidence is found to confirm the patient's complaint of irritation. The perianal skin is often somewhat thickened and thrown into rugae radiating from the anus, with a varying amount of excoriation of the skin or fissuring.

It is cases in this second group which are the great problem as regards treatment. It is probable that a chronic neuritis of the sensory nerves in the anal region is present in most cases of long duration, and hitherto the recognized treatment of cases which have failed to respond to local treatment of the dermatitis has been either (1) operation—Ball's operation or any of the various modifications designed towards sectioning the cutaneous nerves of the anus; (2) the subcutaneous injection of various solutions such as absolute alcohol, quinine-urea, hydrochloric acid, etc.; (3) *x*-radiation.

After working for the last eight years in the out-patient department of St. Mark's Hospital, I have been impressed with the unsatisfactory results generally obtained by these methods. Judging from the number of patients who attend who have previously had one or more courses of *x*-ray treatment, the conclusion is forced upon one that the relief obtained, if any, is often of short duration, and the necessity for repeated courses of *x* rays is dangerous. *X*-ray dermatitis and *x*-ray carcinoma of the anus are well-known catastrophes. As regards Ball's operation, it is true that, if properly done, patchy anaesthesia results at once in the flaps outlined by the operation, but it seldom lasts more than a few months; the extensive wound never heals by primary union, and although there may be relief for a time, the irritation often returns after a few months. There is then quite often the added trouble that an atrophic condition of the skin flaps is liable to develop; the perianal skin within the two curved incisions appears thin, shiny, and discoloured, often with patchy excoriation; this may be partly a trophic condition from section of the sensory nerves, and partly due to the impaired vascular supply; it is, I think, a serious objection to Ball's operation.

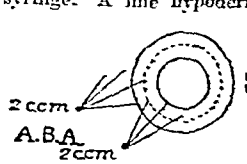
Pruritus being essentially a local condition, it is reasonable to expect a local treatment to relieve it, and subcutaneous injection of an anaesthetic solution appeals to me as being a sensible method likely to succeed. I was therefore greatly attracted by the report of Drs. Yeomans, Gorsch, and Mathesheimer[1] on the use of benacol in the treatment of pruritus ani. This solution was introduced to me last autumn by Dr. Frankfeldt of New York, who very kindly provided me with a supply for trial at St. Mark's. To quote Dr. Yeomans: "Benacol is a solution of equal parts of para-amino-benzoyl-benzoate and phenmethylol in 90 parts of rectified sweet almond oil. It is non-toxic, highly anaesthetic, moderately antiseptic, and, as far as investigated, has a mild depressant action on peripheral nerve endings."

The use of an oily as opposed to an aqueous solution would appear to be particularly valuable as a method of delaying absorption of the local anaesthetic, and therefore

of extending the duration of its action. As an alternative solution to benacol, I have tried and found equally satisfactory a solution known as "A.B.A.," prepared for me by Messrs. Allen and Hanburys, which is now available. A.B.A. is a 3 per cent. solution of anaesthesin with benzyl alcohol 5 per cent. and ether 10 per cent. in sterilized olive oil.

Method of Injection.

The contents of an ampoule of benacol or A.B.A., previously warmed by immersion in hot water, in order to render it more fluid, are drawn into a 2 c.cm. Record syringe. A fine hypodermic needle is attached, and the solution is injected subcutaneously in a fan-shaped manner around and up to the anal margin. The first injection is usually made under the area of maximum irritation. Two ampoules (4 c.cm.) can safely be injected at a time. The injections are usually repeated at intervals of three to seven days until the entire perianal region has been injected, when areas of continued irritation can then be reinjected. I make a practice of charting the injections in a diagrammatic manner (see diagram), which renders it easy to see at a glance the regions that have been injected.



Method of charting injection of left posterior quadrant.

Results.

A slight burning pain has been complained of by some patients either during the injection or some hours later. There has been no general reaction and no complication (particularly inflammation or sloughing of skin) has occurred. No medicinal treatment (bromides, etc.) has been given to any of these patients, and only the simplest applications have been made to the local dermatitis. Sixteen cases have been treated since September, 1928—7 females, 9 males. The irritation in 10 may be classified as severe, in 6 as moderate. The number of sessions has varied from one to six, and the greatest amount of benacol or A.B.A. that any one case has yet received is 22 c.cm., the average being 8 c.cm. It is too soon as yet to speak of "cure," but all of these patients have been relieved, and 8 have been so much improved that they are now practically free from all symptoms. In at least 4 cases with severe dermatitis the visible improvement in the perianal skin has been most dramatic.

The three following cases may be described as examples of the favourable results that have been obtained.

Case 1.—An unmarried woman, aged 28, had suffered from severe pruritus ani, for which Ball's operation was done in February, 1928. Irritation and pain returned as badly as ever within a few months. When seen in September, 1928, she presented a severely excoriated condition around the anus, with numerous fissures. One ampoule of benacol was injected at weekly intervals for four weeks, with immediate improvement; the slightly indurated skin and bright red hyperaemia round the anus was replaced by smooth, pale skin, the fissures healed, and the patient expressed herself as delighted with the improvement. A fifth and last injection was given in November, 1928; she was seen at intervals, and was finally discharged free from symptoms in March, 1929.

Case 2.—A married woman, aged 45, with severe pruritus ani of ten years' duration. She was treated for eighteen months as an out-patient at St. Mark's, with lotions and powders, with no ultimate relief. On September 18th, 1928, benacol 4 c.cm. was injected through four punctures, and on September 25th 2 c.cm. of benacol was injected. Immediate improvement resulted, and continued until March of this year, when a slight return of symptoms made a further injection advisable. I therefore injected 6 c.cm. of A.B.A. posteriorly to the anus, this being the site of slight irritation, and the trouble is again quiescent.

Case 3.—A man, aged 30, with pruritus of four years' duration, treated previously by two courses of x rays and much local treatment, with no real relief. In January of this year 6 c.cm. of A.B.A. was injected at two sessions, and great relief has been obtained. He now has very little trouble.

ANAL FISSURE.

Spasm of the external sphincter ani is undoubtedly the cause of the chronicity of anal fissures, and hitherto the various methods of treatment advocated have in reality been directed—and rightly so—towards relieving sphincteric spasm. These methods may be classified into: (*a*) those which promote relief of pain and consequently the spasm; (*b*) those which attack the spasm first.

Under the first heading are the following favourite methods: (1) insertion of analgesic ointments such as those containing cocaine, anaesthesin, chloretone, opium, and belladonna; (2) local application to the surface of the fissure of an albumin-coagulating agent such as silver nitrate, mercury perchloride, nitric acid, or ichthyol; (3) injection under the base of the fissure of an anaesthetic solution such as quinine-urea. The second method of treatment includes the old operation of forcible stretching of the sphincter muscle under local or general anaesthesia, and the various degrees of "incision" ranging from partial to complete division of the sphincter.

All of these methods have been useful, but the chief drawback has been their unreliability. The palliative methods have often failed to relieve the sphincteric spasm, and I have several times seen a recent fissure—in spite of treatment—gradually become chronic and undermined, until finally operation has had to be undertaken. The operation of divulsion of the sphincter is often successful, but, on the other hand, I have known cases where the fissure has failed to heal, with return of sphincteric spasm within a few days after the operation. The operation of incision of a fissure is a very excellent one when applied to the chronic undermined fissure, and is usually the only certain method of getting these cases to heal, but no one will deny that the after-treatment is a painful one; the wound takes three to five weeks to heal, and it is a severe operation to undertake for a recent fissure.

In the last eight months I have been using benacol and A.B.A. for the treatment of anal fissures, and as an ambulatory method this promises to cure rapidly a very large percentage of cases. It is, in effect, a combination of the two methods outlined above, and consists in the injection of these solutions into the external sphincter muscle and under the base of the fissure.

METHOD.

For treatment of the usual dorsal fissure the patient lies on his right side and the anus is painted with tincture of iodine. A 2 c.cm. Record syringe is filled with A.B.A., and with a hypodermic needle the skin is punctured one inch behind the anus in the middle line. The left forefinger is passed into the rectum as a guide and the needle is thrust deeply into the sphincter, first on one side of the middle line and then on the other, about three-fourths of a cubic centimetre of A.B.A. being injected into each side. The needle is then partially withdrawn and is directed forwards in the middle line under the base of the fissure where the remainder of the solution is slowly injected. This completes the first treatment, but if desired an application of pure ichthyol to the surface of the fissure may be made. In one case in this series I injected an anterior fissure in a similar manner with success.

A varying amount of pain is complained of during the actual injection, but it is seldom severe. Some cases have had pain three or four hours after the injection, but only in a few very nervous subjects has this late pain been at all marked. In every case of fissure injected great relief has been noted, or even complete absence of pain within the first twenty-four or forty-eight hours after the injection.

When re-examined, between the third and seventh days after injection, the local result is invariably very striking. Sphincteric spasm has usually completely disappeared; the finger is admitted readily without pain and the margins of the anus can be separated in a normal manner. In a number of cases at this stage a sentinel pile, if present, has been excised with scissors without further anaesthesia and without more than a faint sensation being noticed by the patient. Pure ichthyol is applied at this stage to the surface of the healing fissure, and the usual course of events now is for the fissure to be found completely healed about two or three weeks after the first injection, with the patient quite free from any symptoms. I do not consider the presence of a small sentinel pile at the outer end

of the fissure to be a contraindication to the use of this method. The sentinel "pile" is usually a small oedematous tag which on several occasions I have observed to disappear when sphincteric relaxation has been obtained by injection of A.B.A. In other cases the tag has subsequently been excised, either without further anaesthesia or after injection of a few drops of novocain. I believe this method will sometimes prove of value even in the case of an undermined fissure; if the sphincter has been made to relax I see no reason why an undermined tag should not be removed locally and successful healing obtained. In a few cases I have given a second injection of A.B.A., but as a rule the relaxation lasts sufficiently long for the fissure to heal, and the spasm then does not return. In one case, described below, injection of A.B.A. was of particular value in that it allowed adequate examination of the rectum (at first impossible on account of pain) to be performed a week later, when a large fibrous polyp in relation to the upper end of the fissure was discovered and accordingly removed. In no case has there been any history of incontinence from lack of sphincteric tone.

The following cases may be taken as representative of the series.

Case 1.—A married woman, aged 30, with a very painful dorsal fissure of eight weeks' duration. She was given an injection of 2 *c.cm.* of A.B.A. One week later the sphincteric spasm had disappeared and the fissure had healed. She was discharged fourteen days after the injection.

Case 2.—A married woman, aged 33, had a dorsal fissure with sentinel tag; duration two weeks; the sphincter was very spastic. On February 19th 2 c.cm. of A.B.A. was injected. On February 26th the sphincter was quite lax, and the patient was discharged on March 12th, the fissure being healed, and the sentinel tag had almost disappeared.

Case 3.—A married woman, aged 29, had a dorsal fissure with spastic sphincter and sentinel tag; duration two years. On January 8th 2 c.cm. of A.B.A. was injected. On January 15th her condition was much improved; the sentinel tag was excised without further anaesthesia. On February 5th no symptoms were present, but a superficial crack was still present; 2 c.cm. of A.B.A. was injected as before. On February 12th the fissure had healed; there was no pain or spasm. She was discharged completely healed on February 26th.

Case 4.—A married woman, aged 42. This patient had a chronic dorsal fissure with large sentinel tag and much sphincteric spasm. On March 12th 2 *c.cm.* of A.B.A. was injected. On March 15th the pain was much less; the sphincter was quite lax, and with a finger a large fibrous polyp in relation to the upper end of the fissure was discovered and readily delivered outside the anus. Novocain was injected at its base, and the polyp excised together with the sentinel tag. On March 26th the anus admitted two fingers readily, and the patient was discharged healed and free from symptoms on April 19th.

To summarize the results: 30 cases from my out-patients' clinic at St. Mark's Hospital and from my private practice have been injected; 18 have been discharged healed, mostly within a period of ten days to three weeks after the injection of A.B.A.; 6 cases remain under treatment. Two cases with indurated fissures were injected with A.B.A., but on further consideration I decided that operation would be more suitable and certain. Finally, 4 cases of recent fissures were injected once, but have not reported for re-examination. So far as I am aware, no patient has had to lie up or discontinue work while under treatment.

Conclusions.

As an ambulatory treatment for pruritus ani the subcutaneous injection of anaesthetic solutions in oil, such as benacol and A.B.A., would appear to be safe, of considerable value, and worthy of extended trial.

In the treatment of recent anal fissures the method described can be promised to effect a rapid and brilliant cure, and this early stage is obviously the best for treatment to be undertaken. In fissures of some duration, relief of pain and healing are likely to be obtained in a considerable proportion of cases.

TREATMENT OF PELVIC INFLAMMATIONS BY DIATHERMY.*

BY

C. A. ROBINSON, B.A., M.B., B.Ch., D.M.R.E.,

PHYSICIAN IN CHARGE OF ELECTRICAL DEPARTMENT, WEST MIDDLESEX HOSPITAL.

THE method of treating pelvic inflammations by a diathermy current passed between electrodes placed back and front may or may not be good, but it is not treatment by heating the pelvic contents. If, during a treatment so administered, a thermometer is placed in the cervical canal, no rise of temperature will be recorded. The method to be described in this paper is one in which the pelvic contents are heated by a high-frequency oscillating current, which is applied by means of an electrode introduced into the cervix or urethra.

The treatment of pelvic inflammations by the diathermy current arose, as will be seen later, out of the method of treating gonococcal infections of the cervix and urethra by this current. Diathermy treatment of cervix and urethra for gonococcal infection was founded upon the known fact that the gonococcus is vulnerable to comparatively slight rises of temperature above the normal temperature of the human body, though whether this is the only factor concerned is open to question. It was known that attempts had been made to free the male urethra from gonococcal infection by means of sounds heated by hot water circulating through them. These attempts failed because the sounds would, of course, not heat the tissues immediately underlying the mucous membrane. These deeper tissues can, however, be heated by a diathermy current to some depth, and it was decided to try the effects of heating them in this way.

Dr. E. P. Cumberbatch, in treating arthritis by diathermy of the joints, had observed that those cases which recovered were always due to gonococcal infection, and that there was no such beneficial effect on other cases of arthritis. As a result, attempts were made to rid the cervix and urethra of gonococcal infection by using the diathermy current, and during 1919 I arrived at the method of heating these tissues by means of metal electrodes introduced into their lumen.

The cervix, being insensitive, can be heated to any required temperature without an anaesthetic, but this, of course, is not so in regard to the urethra. An anaesthetic is undesirable because the patients must be treated as out-patients. The temperature at which the sensation of heat changes to pain is 115° F., and the urethra cannot therefore be heated beyond this without an anaesthetic. Moreover, up to this temperature no inflammatory reaction occurs, and, if it is not exceeded, no pain or discomfort follows the treatment. If it is even slightly exceeded some symptom indicating an inflammatory reaction, such as pain on passing water, will occur on the day following the treatment. No harm results until 131° F. is reached. It seems that the reaction to a temperature up to 115° F. does not set up inflammation, but that an inflammatory reaction begins directly this temperature is passed. As it is necessary in cases of gonococcal infection to treat both urethra and cervix at the same sitting, and inflammation following the treatment is to be avoided, the temperature of 115° F. is taken as the maximum allowable.

It was realized that if this temperature was insufficient the method would fail. There are two factors in the production of the lethal effect on the organism—namely, temperature and time. It was determined empirically that this temperature of 115° F. was sufficient if the length of time during which it was maintained was ten minutes. The number of times the process had to be repeated in the case of gonococcal infection was found to vary considerably, but generally six to eight bi-weekly treatments proved to be sufficient.

The technique now used is as follows: An electrode is introduced into the urethra, and by means of the diathermy current the tissues immediately surrounding the electrode

* Abstract of a communication to the Section of Electro-Therapeutics of the Royal Society of Medicine.

are heated to a temperature which is believed to be 115° F. This temperature is estimated by the patient's own sensation, and is the point where the sensation of heat changes to pain. The insensitive cervix is then treated in a similar manner, the current used to produce the temperature in the sensitive urethra being taken as the standard.

This method of freeing the cervix and urethra from gonococcal infection is very successful; it was first practised nine years ago, and up to the present very few cases refractory to it have been met with. Moreover, I found that in cases of gonococcal arthritis it was necessary to treat the cervix only, recovery of the arthritis then taking place. In 1920 I treated with success cases of arthritis not gonococcal in origin but associated with a cervicitis. In cervicitis due to infections other than gonococcal recovery may be procured and erosions healed, though in such cases a greater number of applications may be required.

French writers on the subject of uterine ionization are always very insistent that direct current applications must never be made if there is any inflammation of the uterine appendages. They state, moreover, that pain in the lower abdomen during such direct current treatments is diagnostic of inflammation of the pelvic organs. Up to the year 1921 I was treating by diathermy cases of cervicitis obtained chiefly from a special treatment centre, and it was obvious that cases of salpingitis would sooner or later arrive. I had treated the cervix in this way both to free it from gonococcal infection and for the effects of this procedure on arthritis, and had noticed that pain in the lower abdomen had occurred during the treatment. This occurred in cases in which other signs of salpingitis were absent. No harm had resulted. However, on September 20th, 1921, a patient came for treatment of vaginal discharge accompanied by definite signs and symptoms of salpingitis.

The patient, aged 31, gave a history of vaginal discharge for many months. Signs and symptoms of salpingitis were present. Gonococci were found in smears of the cervix and urethra. The first application of diathermy was given on September 20th, 1921. After this treatment the patient developed pain in the abdomen, with tenderness and rigidity in the right iliac fossa. Vomiting occurred and the temperature rose to 102° F. The patient was admitted to hospital, where she remained two weeks. By October 4th symptoms had subsided and diathermy was resumed. A week later the discharge was decidedly less, but there was still pain in the lower abdomen and tenderness on deep palpation. On October 14th there was no pain or tenderness. On November 7th, although symptoms of salpingitis had subsided, gonococci were found in abundance in the urethra but not in the cervix. On January 16th, 1922, gonococci were found in the cervix but not in the urethra, and, shortly after this date, treatment was resumed. Applications were made on January 24th and 27th. On February 23rd and March 2nd no gonococci were found in the urethra or cervix. On April 4th they were also absent, there was no discharge, her general health was good, and she appeared to have made a complete recovery. She had then remained free from signs and symptoms of salpingitis for six months from the time when they had first subsided.

In view of this experience I determined in such cases to use a milder degree of heating, hoping thereby that a subsidence of the salpingitis might be produced and that the cervicitis might be satisfactorily treated afterwards. I was at this time familiar with the effects on prostatitis due to gonococcal and other infections of diathermy applied to the prostate by means of a metal electrode introduced into the rectum. Subsidence of pain and frequency of micturition, recovery from arthritis and other metastases, and even recovery of the prostate from the infection were remarkably constant.

The intrapelvic electrode I now use is 1 inch in diameter. It is sheathed in vulcanite except for 1½ inches at the end which is to be in contact with the upper end of the vagina. This end must be rounded so as to give an even distribution of the current on account of the tendency high-frequency currents have of coming off at points or edges. The indifferent electrode used at present is a lead belt, 2½ inches wide, made of one pound of lead (gauge 24 S.W.G.) and fastened by a clip, which also serves for an attachment to the machine. With these electrodes a current of two amperes gives a temperature of 106° F. in the tissues in the neighbourhood of the metal part of the vaginal electrode. How quickly the temperature falls off from one electrode to the other is not known, so that the actual heating of the tubes and ovaries cannot be determined. The treatments last twenty minutes each, and are given twice a week.

The cases about to be tabulated and described were sent for treatment by one of the gynaecologists at St. Bartholomew's Hospital, from Dr. Malcolm Donaldson's department, by Dr. Wilfred Shaw, Mr. Lane Roberts, and Mr. Burt-White, and by Dr. Oldershaw from the Soho Hospital for Women. I am indebted to Dr. Oldershaw for his interest, kindly criticism, and help, and for some of the reports on the late results of the treatment. The total number of patients was 57, but, excluding 4 found unsuitable for treatment, 6 who attended for only one or two treatments, and 6 who received only a short course of treatment, the number may be reduced to 41. Of these, 33 recovered (about 80 per cent.), 6 were partially relieved of their symptoms or relapsed after apparent recovery, and 2 were unrelieved.

When cases are described as recovered it means that: (1) They are relieved of symptoms connected with the pelvic condition. Many of these patients have been complaining of symptoms for a long time, and their frame of mind is such that recovery from pelvic inflammation is not immediately followed by subjective improvement. Pains, discomfort, or headaches are enlarged upon on inquiry as to their present condition. They are regarded as recovered only if they are relieved of those symptoms which can be referred to pelvic inflammation. (2) Their general health is markedly improved. Instead of having a toxic appearance and being worn out from pain and sleeplessness they have the appearance of health, sleep well, and have improved appetite. (3) Physical signs of pelvic inflammation are absent; examination reveals no swelling which is tender on manipulation. Though there may be some thickening or other abnormality which the examining hand can still detect there is nothing which could be considered sufficient to justify the assertion that recovery has not taken place. In some cases, so far as can be ascertained by inspection and palpation, a complete return to normal has occurred. The appearance of the cervix is normal, and the erosion is healed.

The treatment is safe. No harm has ever resulted, except the acute exacerbation of the symptoms referred to as occurring occasionally when treating the cervix. No patient has died under the treatment, and no operation has become necessary as a result of it.

In the following tables the description of each case is necessarily very brief. Ip. indicates the mild heating by

TABLE I.—*Salpingitis of Undetermined Origin.*

Case No.	Remarks	Treatment.	Results.
50	Tense, tender mass Douglas's pouch, 3 months	Ip. 3	Pain relieved, still tender, operation.
51	Inflamed left appendages. Duration 2 years	Ip. 10, interval 2 months, Ip 9	Recovery. Slightly tender nodule in left fornix.
55	Right tube and ovary inflamed, 3 months	Ip. 12	Recovery. Pregnant
85	Inflamed right ovary and tube, 18 months	Ip 12	Recovery Followed one month.
116	Fluctuating swelling. Cervicitis, 18 months	Cerv 5. Ip. 3	Recovery
209	Both tubes enlarged, left is tender	Ip 10	Recovery.
389	Left tube and ovary enlarged and tender	Ip 10	Recovery.
407	Salpingitis. Cervicitis erosion, 6 to 7 years	Cerv 4. Ip. 2	Recovery.
441	Salpingitis Cervicitis erosion, 2 years	Ip. 3. Ions. 11	Recovery.
558	Dry pyosalpinx. Cervicitis, 6 years	Ip. 11	Recovery.
112	Double salpingo-oöphoritis	Ip. 5	Recovery.
108	Tender mass right fornix. Cervicitis	Ip 15. Cerv. 3	Recovery. Subjective symptoms remain.
433	Tender mass both iliac fossae. Cervicitis and erosion	Ip. 5. Cerv. 3. Ip. 5	Recovery. Subjective symptoms remain.
485	Double salpingo-oöphoritis. Cervicitis and erosion	Cerv. 20	Recovery; 9 months later well; 7 months preg.
599	Salpingitis and cervicitis	Ip. 12. Ions. 5	Recovery. Relapse of cervicitis.
160	Swelling right tube, less so left. Cervicitis	Ip. 10. Cerv. 5	Recovery. Followed two months.
528	Cervicitis, subsiding salpingitis, left	Ip. 9. Cerv. 3	Recovery.

the vaginal electrode, and cerv. means that the cervix has been especially treated. The total duration of the course of treatments may be roughly reckoned by remembering that the applications are made twice a week.

In Case 441, healing of the erosion was produced by ionization, which in some cases is more effectual or more rapid than diathermy. Of the seventeen cases, twelve have recovered; one had three treatments only, and the result is inconclusive; three made partial recovery, and one had a relapse of the cervicitis.

TABLE II.—*Cases in which Gonococcus was Found.*

Case No.	Remarks.	Treatment.	Result.
395	Salpingitis. G. found	Cerv. 5	Recovery. Observed six months.
162	Fluctuating swelling. G. found in cervix and urethra	Ip. 1. Cerv. 3. Ip. 6	Recovery. Followed one month. No relapse.
540	Arthritis and salpingitis. Aged 8 years	Ip. 8. Per rectum	Recovery. No arthritis, no salpingitis. Followed five months.
165	Appendix. Right tube and ovary removed, tender swelling left fornix	Ip. 5. Cerv. 3	Recovery.
282	Enlarged thyroid and salpingitis. Cervicitis	Ip. 4. Cerv. 8	Recovery. Thyroid not enlarged.
301	General peritonitis 7 months ago with inflammation of tubes and ovaries	Ip. 3. Cerv. 3	Recovery. Followed three months. Five examinations. No Gonococcus found.
223	Gonococcus found in pelvic pus of peritonitis. Pain and tenderness. Rigidity right iliac fossa	Ip. 11	Recovery.

Cases proved to be due to gonococcal infection all made a good recovery after a comparatively short period of treatment. This is nothing more than anyone familiar with the effects of diathermy treatment of gonococcal infections would have predicted, and requires no special treatment.

TABLE III.—*Following Confinement.*

Case No.	Remarks.	Treatment.	Result.
184	Cervicitis 2 years. Tender swelling left fornix	Cerv. 4. Ip. 12	Recovery.
84	Pain 2 years. Both appendages large and tender	Ip. 11	Recovery.
359	Pain one year. Left salpingo-oöphoritis. Cervicitis. Erosion	Ip. 1. Ions. 9	Recovery.
503	Pain 4 years. Tenderness both iliac fossae. Cervicitis	Ip. 2. Cerv. 7. Ions. 3	Recovery.
168	Bilateral-salpingo-oöphoritis	Ip. 8	No improvement.
375	After miscarriage 2 months ago. Swelling right fornix. Cervicitis and erosion	Ip. 5. Cerv. 3. Cerv. 11	Recovery. Relapse of cervicitis after 14 days. Curetted.
514	After miscarriage 3 years ago. Swelling left fornix	Ip. 8	Still has pain Failure.
7	Pain 2 years. Erosion and cervicitis	Cerv. 7	Recovery; 7 months later still recovered.
36	Post-puerperal. Swelling right fornix. Cervicitis	Cerv. 3. Ip. 16	Recovery. Followed one month.
137	Followed miscarriage. Tender swelling left fornix	Cerv. 3. Ip. 11	Recovery; 4 months later well and preg.
210	After confinement 5 years ago. Salpingitis	Ip. 7	Recovery; 5 months later 2 months preg.
295	After confinement one year ago. Salpingitis	Ip. 11	Recovery.

The cases occurring after confinement made a good recovery as a rule; they all had physical signs of salpingo-oöphoritis. Cases 168 and 514 definitely failed to improve after a month's treatment. I have no explanation of why this is so, or in what respect they differed from the rest. In one case (375) the cervicitis and erosion relapsed. The patient appeared recovered on January 6th, 1928, and again on February 21st. She was not seen again till October, when she gave a history of having been curetted in the meantime. There was a bright red rim round the cervical os, which returned to normal after a few diathermy treatments. The salpingitis had not relapsed.

TABLE IV.—*Parametritis, with Deep Lacerations.*

Case No.	Remarks.	Treatment.	Result.
567	Left parametritis. Two years' duration	Cerv. 3. Ip. 6	Recovery.
562	Parametritis	Ip. 4	Recovery incomplete. Was to have attended as an out-patient, but did not do so.

TABLE V.—*Following Operation for Ectopic Foetation.*

Case No.	Remarks.	Treatment.	Result.
524	Six to seven months after operation	Ip. 3	Relief of symptom. She was to have attended as out-patient, but did not do so.
418	Tenderness and swelling left ovary and tube. Operation 10 years ago	Ip. 8	Recovery.
576	Large hard tender mass low down in Douglas's pouch. After operation 12 months before. Thin, ill and toxic-looking	Ip. many	Small, hard, not tender swelling can still be felt. General health good.

Conclusions.

The cases likely to recover after a comparatively short course of treatment are those of chronic salpingo-oöphoritis without rise of temperature or constitutional disturbance. The pain in one or both iliac fossae may be severe, and there may be a considerable degree of ill health due to pain, sleeplessness, and toxaemia. The presence of pus is not necessarily a contraindication. The chronic pus tube may disappear as far as physical examination goes. Cases are likely to do well if there is evidence of infected cervix *with or without erosion, and especially if there are* gonococci present.

From the point of view of the effect of treating the cervicitis the figures are very striking. Twenty-five cases have been associated with cervicitis, but one of them received only three treatments. Of the remainder, twenty-two have recovered of the salpingitis, but two of them have had a relapse of the cervicitis. Two recovered as far as physical examination was able to establish the fact, *but* subjective symptoms remained. *If the cases in which cervicitis occurred are included in the failures, we have* twenty successes, two failures, and two doubtful successes, out of twenty-four cases.

The treatment of gonococcal salpingitis and ovaritis consists in most cases in the treatment of the cervical infection. This applies also to many cases of salpingitis due to infection other than gonococcal. The treatment of the cervix should not as a rule be proceeded with forthwith, *but be* preceded by a few applications of intrapelvic heating. If treatment of the cervix is undertaken when salpingitis of any degree of severity is present great increase of pain with rigidity of abdominal walls and rise of temperature may result. This condition may last a fortnight, and has occurred in two or three of the cases. No harm has resulted, and the cases have all been eventually cured. It will be noticed from the tables that some of the cases make a rapid recovery *even if the symptoms have existed for* years. It is probable that 80 per cent. of recoveries would be obtained if gynaecologists chose the cases with a knowledge of what may be expected of the treatment and, while giving a chance to cases on the borderline, exclude those which are obviously unsuitable.

A follow-up of cases treated within the last two years *has been carried out by Dr. Simon, and in 80 per cent.* of those from whom answers were received recovery was confirmed.

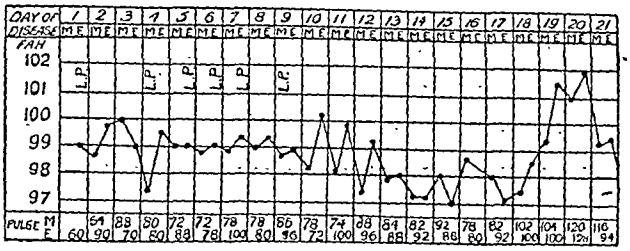
These chronic pelvic infections and inflammations have always presented a difficult problem in gynaecology. I believe that diathermy offers a new method which will avoid a long and tedious period of treatment with swabs, tampons, and douches, will render mutilations unnecessary, and will bring about recovery in some cases in which operation is not likely to succeed.

both hands was very weak, but the legs moved normally. No sensory abnormality to pin-prick or light touch could be found. His systolic blood pressure was 140 mm. of mercury. Morphine and hyoscine were given repeatedly for the pain and restlessness.

On the following day he had improved, but he had retention of urine for twenty-two hours; catheterization was not necessary.

From May 26th to 29th lumbar puncture was performed daily. The pressure and the proportion of blood were less on each occasion. On May 30th his reflexes were as before. The reaction of the pupils to light was sluggish, and the left disc appeared to be paler than the right. The next day lumbar puncture produced only a few drops of opalescent fluid. The patient still needed morphine.

Epistaxis occurred on June 1st, after which his blood pressure came down to 115. The reducing substance was by this time absent from the urine. From then until his discharge on July 4th recovery was steady with the exception of a relapse from



L.P.=Lumbar puncture.

June 9th to 11th. On these days his temperature rose to 102°-103°. The patient vomited and complained of severe headache. The pulse, which had previously been varying between 60 and 96, increased during the fever to as much as 128. The attack subsided without a lumbar puncture.

On discharge the central nervous system appeared to be normal, except for the increase of the left plantar reflex and the left pupil being larger than the right. Three weeks later the same signs persisted. Headaches were still present on exertion, but less severe.

Commentary.

Previous cases seen at necropsy or during operation have been found to have an aneurysm which has ruptured into the subarachnoid space at the termination of the internal carotid artery. The aneurysms have been considered to be congenital in origin.

Typically there is no evidence of syphilis, no history of trauma, the blood pressure is not necessarily high, and the patient is younger than the usual victim of a vascular intracranial lesion.

Features at the time of the attack to which Symonds draws attention are:

1. The sensation of something snapping at the base of the skull.
2. Brief initial loss of consciousness followed by a dazed "wandering" state.
3. Intense pain at the back of the neck associated with stiffness.

The case recorded in this note is that of a young healthy patient. The cerebro-spinal Wassermann reaction was negative. The highest blood pressure recorded was 140 mm. of mercury, but this was, of course, after the haemorrhage. The patient had a definite history of trauma; but this was eight years before and he had been perfectly well in the interval.

The attack began with sudden severe pain at the back of the neck and with sudden collapse. The period of unconsciousness was brief. Possibly this was due to early lumbar puncture. The patient subsequently complained of severe occipital headache and stiffness of the neck. The pain and stiffness of the neck were very marked; and his refusal to grip with his hands and the pain on movement of his shoulders are further evidence of irritation in the cervical region.

That the haemorrhage was not intracerebral is shown by the absence of localizing signs at the outset and the almost complete absence of residual lesions. The proportion of blood in the cerebro-spinal fluid leaves no doubt that the haemorrhage must have been extensive. Had it been intracerebral a haemorrhage of this size would almost certainly have left more definite residua. The only residual sign was the slight inequality of the pupils, which may reasonably be attributed to organization of blood clot round the third nerve at the base of the brain.

It is interesting to note the rise in temperature during the relapse, and that it was associated with increased pulse rate, not with the slow pulse of increased intracranial pressure.

Summary.

1. A case is reported of extensive intradural haemorrhage with sudden onset accompanied by collapse and signs of increased intracranial tension and of irritation at the base of the brain.

2. The lesion occurred in a young and healthy man, and is not attributed to trauma, infection, or heart or kidney disease.

3. Recovery occurred without appreciable residual lesion.

4. The diagnosis made was rupture of an intracranial aneurysm into the subarachnoid space.

My thanks are due to Dr. J. V. C. Braithwaite for permission to record this case.

A RAPID METHOD OF TREATMENT IN PERFORATED DUODENAL ULCER.

BY

C. J. CELLAN-JONES, M.D., F.R.C.S.Ed.,

ASSISTANT SURGEON, SWANSEA GENERAL HOSPITAL.

SURGICAL intervention, in so grave an emergency as the perforation of a duodenal ulcer, demands a variety of operative technique which combines speed and simplicity so that the degree of shock already existing shall not be made more profound by prolonged manipulation or anaesthesia. At the same time it must be remembered that a crisis has been reached in the history of the ulcer, and that, successfully treated, it may now undergo a spontaneous cure, relieving the patient of all his previous symptoms. Bearing this fact in mind, it is important that the operation shall be carried out in such a manner as to cause a minimal degree of narrowing of the duodenum, so that the necessity for performing a gastro-jejunostomy, either immediately or at a later date, shall seldom arise.

The method adopted by most surgeons when closing a duodenal perforation consists in the application of a purse-string suture or of a number of Lembert's sutures in the vicinity of the crater with a view to infolding its margins completely. With this aim accomplished, the operation is concluded, commonly, by the application of an omental graft. If the lesion is of some chronicity, it is also necessary either to excise the friable margins of the ulcer or to insert the sutures at least one-half to three-quarters of an inch from the actual gap, so as to prevent the catgut, when it is tied, from cutting through.

The main criticism which attaches itself to the above procedure is the degree of constriction of the duodenum which it necessarily engenders, and which is a much more fertile cause of a permanent stenosis than the fibrosis and contraction of the ulcer. I have proved to my own satisfaction that a higher percentage of successful results is obtainable when constriction of the duodenal lumen is reduced to a minimum.

The method of operation about to be described has been employed on fifty-one occasions during a period of three and a half years. It can be performed with greater rapidity and has yielded uniformly satisfactory after-results, since in only one instance among forty-two successful cases has a subsequent gastro-jejunostomy been found necessary.

The abdomen is opened by an incision three to four inches in length, situated above the umbilicus and about one inch to the right of the middle line. The stomach is identified and grasped by a protected clamp, applied over a saline towel. The clamp provides an opportunity for gentle traction, which is usually capable of bringing even an awkwardly situated perforation into comparative proximity with the edges of the wound.

Varying with the size of the perforation, some four to six sutures (catgut size 000 on a 30 *mm.* half-circle Souttar needle) are now rapidly inserted. All coats of the gut are invariably penetrated, and at least two sutures traverse the

floor of the aperture, entering and leaving the serous surface approximately a quarter of an inch from the margins of the ulcer. The remaining sutures occupy positions a little to the gastric and duodenal sides of the ulcer, and in each case the ends of the stitches are grasped by a pair of light forceps. The effect produced is that of an archway of sutures placed in the long axis of the gut and extending on each side for at least three-quarters of an inch beyond the ulcer cavity.

A long omental strand, of not too slender proportions, is now sought out and a fine suture passed through its extremity. Forceps readily draw the suture and omentum through the archway, and the tip of the strand is finally anchored by a couple of stitches to the serous and muscular coats in the region of the pyloric antrum. The sutures forming the archway are now tied off; those beyond the margins of the cavity are firmly knotted, whilst quite a fair degree of tension can be placed upon the stitches traversing the crater since the omentum behaves as a soft resilient cushion, which prevents the catgut from cutting through the rigid tissues.

When it has been established that the new attachment of the omentum has left no loop which might strangulate a segment of the intestine, the gastric clamp is removed and the abdominal contents are replaced. The peritoneal cavity is gently swabbed until it is fairly dry, and if perforation has preceded operation by a longer period than twelve hours suprapubic drainage is instituted, otherwise the incision is simply closed in layers.

On theoretical grounds it might be argued that this method should not succeed, since it strangulates the omentum over an area where infection is distinctly liable, and hence that sloughing and reopening of the crater should be the outcome of the procedure. In no instance, however, has this accident occurred, and an opportunity was given for observing the late results of the operation when a patient, who had been operated on two years previously, underwent laparotomy for cholelithiasis. In this case the ulcer seemed to be completely healed, the duodenum exhibited little evidence of scarring, and was merely thickened somewhat over the portion of the outer wall where the omentum had been applied. Local adhesions were conspicuous by their absence.

An immediate mortality of 17.6 per cent.—nine cases out of a group of fifty-one—has already been admitted in an earlier section of this paper, and calls for some further explanation. In one instance only did death occur when operation followed within twelve hours of perforation. In two cases from sixteen to eighteen hours had elapsed, whilst in two others there was an intervening period of more than twenty-four hours. The remaining fatal cases were not operated upon until more than forty-eight hours after perforation, when well-marked peritonitis was already established.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FRACTURE OF ANTERIOR ILIAC SPINE.

THE following case seems to be worth recording since I can find only one reference to this condition in the literature at my disposal—namely, in Wilson and Cochrane's *Fractures and Dislocations*, 1929.

A strong young man, aged 19, had been practising for some sports, and had taken part in putting the weight and high and long jumping. He then tried a hundred yards sprint, but after travelling some seventy-five yards he felt "something give," and had severe pain in the groin, causing him to fall. He was raised to his feet, but could not flex the right thigh.

When examined he was found to have perfect passive movement of the knee and hip, but hyperextension of the thigh produced slight pain in the right groin. On walking he had to drag the right limb forward, being unable to lift the foot off the floor, unless by great effort. On deep palpation over the anterior part of the iliac crest, something was felt to slide backwards and forwards, and as the anterior superior spine was ill defined, the diagnosis of avulsion of the anterior superior iliac spine by the sartorius muscle was made. This was confirmed the following day by an x-ray examination, when the spine was found to be lying about one inch below its normal situation with the patient in the recumbent position.

The interest of this case seems to lie in the fact that the patient was using the sartorius to a less extent while running than while long jumping, etc., and secondly in the comparative rarity of a fractured anterior superior spine by indirect violence.

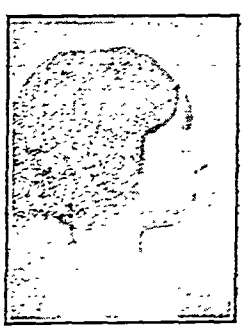
Gravesend. JAMES CRAWFORD, M.B., Ch.B.Ed.

CERVICAL SUBLUXATION FOLLOWING ANAESTHESIA.

THE following case seems of sufficient interest to warrant recording.

Last February the patient, a girl aged 9, was operated on in hospital under general anaesthesia. When her parents took her home they stated that her head was twisted and "stuck to one side." She was taken to one of the Royal National Orthopaedic Clinics (operated in conjunction with

Before operation. After operation.



Before operation. After operation.

local authorities) and on examination it was seen that her head was bent towards the left shoulder and the face twisted towards the left side. The right scalenes were prominent and spasmodically contracted, the right and left sterno-mastoids prominent, though relaxed, and the child could not move her head. She complained of a dragging pain radiating towards the left shoulder. Stereoscopic x-ray photographs were made, but they afforded no help in diagnosis. A tentative diagnosis of a subluxated cervical vertebra was made, and the child admitted to the country branch of the hospital at Stanmore.

At the operation, which was performed six weeks after the onset of the symptoms, the head was found to be fixed in the deformed position, a transverse process on the left side being unusually prominent. On palpation of the pharynx, a hard bony mass was felt projecting posteriorly and to the left, at about the level of the top of the left tonsillar fossa. Reduction was attempted by extension and manipulation, with apparent success. There was no "click," probably owing to the presence of adhesions and to the length of time that had elapsed, but after the manipulation the bony mass felt in the pharynx was median in position and no longer prominent. The child has regained a full range of movements without deformity.

I have to thank Dr. C. W. Durward for excellent photographs of the patient, taken before and after operation.

STILLBIRTH AND NEO-NATAL DEATH.

AT a meeting of the Edinburgh Obstetrical Society held on May 8th, with the president, Dr. HAIG FERGUSON, in the chair, Dr. CHALMERS FAHMY and Dr. ELSIE CROWE presented a communication on "Stillbirth and neo-natal death." The paper was based on a study of 300 cases from the Royal Maternity and Simpson Memorial Hospital, Edinburgh. Of the total number, 248 foetuses were born at, or near, full term, while 52 were definitely premature. In order to keep in prominence the clinical aspect of the investigations, the cases were discussed according to the manner of delivery, the stillbirths and neo-natal deaths being dealt with separately in each group. Detailed microscopical reports were not included in the paper, though histological examination of a great many foetuses had been carried out. The 248 cases of foetuses born at, or near, full term were discussed according to the following table.

Management of Labour.	Stillbirths.	Neo-natal Deaths.	Macerated.	Total.
Spontaneous delivery (all vertex presentations)	47	16	28	91
Forceps	54	7	4	65
Breech	47	4	5	56
Caesarean section	8		0	13
Craniotomy	23	0	0	23
Totals	179	32	37	248

Special reference was made to the occurrence of intracranial haemorrhage, and its frequency in cases of normal spontaneous delivery was emphasized. There were 47 stillbirths in the group of spontaneous delivery (all vertex cases). Of this number, 11 deaths were due to intracranial haemorrhage, and 15 (in 8 of which some intracranial haemorrhage was also found) to asphyxia.

Acute anaemia was thought to be the cause of death in four instances. In each of these labour was complicated by ante-partum haemorrhage, and no cause for death was found other than the pale and anaemic state of all the foetal organs. Clinical histories were quoted of cases of easy labour in which death was due to intracranial haemorrhage. It was pointed out that in parous women the foetal head may be driven right through the pelvis from brim to outlet in a short space of time after rupture of the membranes, and that such rapid descent may predispose to the occurrence of haemorrhage. Such a rapid passage of the head was not dissimilar to that occurring during a breech delivery, which was known to predispose markedly to cranial injury. The number of neo-natal deaths in infants born at, or near, full term was 16, and of this number 7 were due to intracranial haemorrhage. The association of intracranial haemorrhage with asphyxia was noted. In many cases it was difficult to say which factor predominated, but stress was laid on the fact that the two conditions were frequently found in combination. The recognition of this fact was important clinically, for it pointed clearly to the need for treating asphyxiated infants with great gentleness, whether they were born white or blue. That infants born pallid should be treated as if in a condition of shock was well recognized, but the speakers did not think that equal care had hitherto been deemed necessary for those born in the state of blue asphyxia. Such infants, too, might be suffering from intracranial haemorrhage, and accordingly methods of artificial respiration, such as Schultze's and Byrd's, should not be practised. Attention was also drawn to the occasional finding of intracranial haemorrhage with pulmonary disturbance in the infant surviving only a few days. It was thought that the haemorrhage, by depressing the respiratory function, might predispose to partial atelectasis and also to patches of pneumonia.

Ureteric Dilatation and Pyelonephritis of Pregnancy.

Mr. D. STEWART MIDDLETON communicated a paper on "Ureteric dilatation of pregnancy: its complications and sequelae."

Mr. Middleton began by discussing the question of the dilatation of the ureters which is commonly associated with pregnancy. This dilatation had only been noted up to the last few years in post-mortem specimens, but latterly by pyelo-ureterography; thus it could be demonstrated that this was a condition that occurred in about 85 per cent. of pregnant women. The right ureter was usually affected alone, but both ureters might be affected—the left ureter becoming dilated at a much later date in the pregnancy. The etiology of dilatation of the ureter was discussed, and Mr. Middleton strongly favoured the theory that the ureters were affected by the same forces that had been acting on the uterine musculature throughout pregnancy—namely, muscular hyperplasia combined with diminished contractibility. The greater dilatation on the right side might be accounted for by torsion of the uterus. During the puerperium the muscular hyperplasia would, of course, retrogress, and mobility would be re-established immediately after delivery. It was clear that this thickened ureter, already the seat of connective tissue hyperplasia, and exposed to what must constitute a considerable degree of trauma during labour, would be liable in certain cases to become the seat of sufficient fibrosis to cause ureteric stricture, thus perpetuating what was otherwise a temporary hydro-ureter.

Mr. Middleton then went on to discuss the question of acute pyelonephritis of pregnancy, which, in his opinion, was due to chronic colonic stasis, which allowed the absorption of *B. coli* from the colon, and resulted in the infection of a vulnerable dilated ureter during the process of excretion of these organisms from the blood via the renal tract. In regard to treatment, he suggested that raising the foot of the bed might have a beneficial influence by decreasing any tendency to pressure on the lower ureter by the lower pole of the uterus. The majority of cases of pyelitis responded to simple treatment; but in more serious cases the dilated ureter had to be drained, and it was now seldom necessary to induce abortion or premature labour in cases of pyelitis. At the same time, measures should be taken to treat the stasis in the proximal colon wherein lay the origin of the infection. Idiopathic haematuria of pregnancy was next discussed, and was thought to be due to a compression of the veins in the renal pelvis, with a corresponding rise in the arterial tension. This would give rise from time to time to rupture of a small vessel. Mr. Middleton gave details of four cases of haematuria during pregnancy, and showed that catheterization of the ureter and aspiration of the renal and ureteric residual urine would, as a rule, cut the haematuria short. With regard to ureteric stricture, Mr. Middleton was inclined to emphasize the close association of stricture with multiparity. Before coming to this conclusion Mr. Middleton collected all the pyelograms made in the electric diagnostic theatre of the Royal Infirmary which showed a dilatation of the ureter due to stricture. On going thoroughly into the case of each of these pyelograms it was found that all occurred in multiparae, the dilatation in all but two being confined to the right side. This distribution of dilatation corresponded accurately with that of the simple dilatation of pregnancy. None of the cases had suffered from acute pyelitis during pregnancy, but the symptoms could be traced to having occurred shortly after a confinement. Mr. Middleton thought that stricture of the ureter gave rise to two clinical syndromes: (1) idiopathic haematuria of pregnancy; (2) pain in the renal region, usually on the right side, occurring in a multiparous woman, varying from a mild backache to pain so severe as to suggest renal colic. The pain often began during a pregnancy as backache, and became intensified during successive pregnancies. In more than half the cases no abnormality would be found in the urine, and the decision to proceed to a routine urological examination had to be based on consideration of the symptoms, and not on examination of the urine.

TREATMENT OF OESOPHAGEAL CANCER BY RADIUM.

AT the summer meeting of the Section of Laryngology of the Royal Society of Medicine on June 7th, with Mr. H. BELL TAWSE in the chair, a communication was made by Mr. F. J. CLEMINSON on the treatment of carcinoma of the oesophagus by radium.

Mr. Cleminson said that early last year two papers appeared which, taken together, suggested to him that it might be possible to improve the treatment of carcinoma of the oesophagus. The results in this field could hardly be worse—the mortality had been 100 per cent. in the hands of almost every worker—and there was always a chance that they might be improved. He therefore determined to try the method of bringing about lung collapse on one side and afterwards of practising a thoracotomy with a view to placing radon seeds in the periphery of the growth. Radon (radium emanation) was chosen rather than radium to obviate the necessity of subsequent removal. So far the method had been tried in three cases, which he described in detail. The first was a nervous man, aged 74, who was seen on June 12th of last year. For three months he had complained of a little indigestion and difficulty in swallowing. An *x*-ray film showed an irregular stricture at the level of the fourth to the sixth dorsal vertebra, strongly suggestive of malignant disease. A portion removed for histological examination showed active carcinoma, with many of the cells undergoing mitosis. On June 28th, the lung having previously been collapsed, the left side of the chest was opened, when an excellent view of the mediastinum was obtained, but it was not possible actually to feel the growth. Twenty unscreened radon seeds, each containing 1.2 millicuries of the radium emanation, were implanted by means of a curved needle and trocar, being distributed around the inferred position of the growth. About seven to ten days afterwards there was a distinct improvement in the swallowing, but pleural effusion formed and delayed convalescence. This was probably due to the fact that the seeds were unscreened, with consequent irritation from the alpha and beta rays. On August 21st a platinum-screened tube of radium, with an effective length of 2 in., and containing 50 millicuries, was passed through the oesophago-cope into the lumen at the position of the growth and left for twenty-four hours. The patient remained well for a time, but seven weeks later he had lost a good deal of ground, swallowing became very difficult, large quantities of sputum were brought up, and on November 8th he died. The second case was a man aged 58, first seen on July 24th. He had difficulty in swallowing, and there was an irregular stricture at about the level of the arch of the aorta. The oesophagoscope revealed an ulcerated growth, which had all the appearance of a carcinoma. A specimen was obtained later which showed carcinoma of the squamous-celled type. An artificial pneumothorax was induced, and afterwards on the same side a thoracotomy was done, giving a good view of the mediastinum. Again twenty radon seeds, each containing 1.3 millicuries, and having platinum screens, were inserted. The growth could not be felt, but, its position being known, the seeds were disposed around that area. On the fourth and fifth days the temperature rose to 101° F., and there was a moderate pleural effusion. Four weeks after the operation the patient went to a convalescent home, and marked improvement in the swallowing was evident. Six weeks later swallowing was not so good, and the radiogram revealed obstruction below the level of the aortic arch. A platinum-screened tube, of 2½ in. effective length, and containing 38.8 millicuries, was passed into the oesophagus, and kept there for a time, after which the patient got better, but later relapsed and died, the post-mortem examination revealing carcinoma on the left side of the oesophagus, about 4 in. in extent. It was noticed that certain of the implanted seeds were missing, and it was clear that through an abscess which had formed or by some other means they had got access to the lumen of the gullet and escaped. In the third case it was decided that less radon should be used in order to diminish the chance of the necrosis of tissue consequent upon the crowding of the seeds together. This was the case of a man, aged 61, with a history of dysphagia for five months. He was seen on February 1st of this year, when it appeared that there was a stricture at the level of the fourth dorsal vertebra. The growth proved to be a squamous-celled carcinoma. The lung was collapsed on the right side, thoracotomy was done, and 16 radon seeds inserted, representing a total dose of 19.8 millicuries. This man was a bronchitic individual, and ran a hectic temperature for some time afterwards, dying about five weeks after the thorax had been opened. It was too early to say yet, Mr. Cleminson concluded, that this technique was likely to produce a cure in any case.

Oesophageal growths were notoriously refractory to radium, but the purpose of his communication was to call the attention of other workers to this method, and so prepare them for the time when possibly something of real value might come along this line of investigation.

Mr. MUSGRAVE WOODMAN (Birmingham) also gave a brief account of some similar work which was started last November. It had been felt that the application of large doses of radium centrally in these growths must definitely fail, because the substance was in contact with the necrotic centre of the growth and not with the growing edge. The advantage of the radon was that time limited its activity—at the end of a week it was quite inert—and also that the small seeds were very easily inserted. There had never been any local inflammatory reaction, nor any general reaction, nor any immediate mortality in the thirty cases in which the method had been tried. The general improvement in swallowing was quite considerable. At the end of a month after the first application of the radon there was found invariably a regeneration of the epithelium, a diminished vascularity, an increase of fibrous tissue, and an improvement in the upper part of the stricture which it had been possible to reach. The speaker illustrated his cannula and trocar for implanting the seeds, and described two cases, one of which was still well six months after one application of radon; the other, after some improvement, had died of ascites. The surgery of the oesophagus was very difficult, but he looked forward to the time when this part of the alimentary tract would be dealt with as easily as the rectum.

Mr. THACKER NEVILLE also read a note in which he reported on two cases treated by radon inserted into the growth; the patients lived for about five months.

The PRESIDENT said that a great deal more work needed to be done on this subject, especially in the way of improvement in the technique of thoracotomy, but the future seemed to him to hold out a chance of cure by the combination of operation with radium insertion.

EXPLORATORY OPERATIONS AND THEIR JUSTIFICATION.

AT a meeting of the West London Medico-Chirurgical Society on June 7th, held at the West London Hospital, with Dr. H. H. SANGUINETTI in the chair, a discussion took place on exploratory operations and their justification.

Mr. DONALD ARMOUR, in opening, said that he had searched the Oxford Dictionary for a proper understanding of the word "exploration," and found its medical and surgical connotation given as "the examination of an organ, wound, etc., by the use of the finger, probe, or other physical appliance." Before undertaking such an exploration the surgeon must be able to show the reasonableness of his action. The tendency to perform exploratory operations was fostered by the element of uncertainty in medicine and the comparative safety of operations to-day, but an exploratory operation should not be used as a labour-saving device nor as a short cut to a diagnosis. Surgical skill and safety must not be allowed to weaken surgical conscience and judgement. Rather should every clinical means be used to make diagnosis more accurate, treatment more beneficial, and prognosis more positive. No one would question the advisability or justification of operations distinctly indicated for the relief of conditions only to be treated surgically, and in which the exploratory element was only of minor importance in the diagnosis; but when

the exploratory element became more pronounced, and the benefit to be derived more problematical, the justification became more difficult. From the ethical point of view there were justifiable and unjustifiable operations. The first were carried out in cases in which the diagnosis or surgical indications remained obscure, but in which the operation promised benefit to the patient, either through the relief of suffering or the averting of impending danger. Unjustifiable operations were those in which there was no real promise of facilitating a diagnosis, or of lessening suffering or warding off peril, and in the hands of the unscrupulous such operations might become reckless and sometimes even criminal.

Dr. J. A. RYLE laid it down that exploration should be the last method of approach to a diagnosis, and never undertaken lightly. The justification varied with the circumstances of the case, with the age of the patient, for example, and with the facilities for keeping observation on the patient and the availability of specialist colleagues. The increased precision of clinical diagnosis, both in acute and chronic abdominal disease, had, largely through the contributions of surgery, greatly diminished the need for exploration. Nevertheless, it would be generally agreed that the exploratory laparotomy could not be excluded. The exploratory operation might be the mature decision of a wise and careful man or the crude resort of an ignorant and baffled man. Exploration was justified when strong fears were entertained as to the presence of organic disease of a kind requiring surgical relief, while no determining evidence of its presence or nature was otherwise possible; also in the case of palpable tumours of uncertain nature when there was obstruction which might be due to growth in the head of the pancreas or to impacted gall-stones, for example; or again, when organic disease was known to be present and its nature had been determined, but there was uncertainty as to operability. This last applied to many growths of the stomach and colon, where diagnosis might be established with considerable confidence, and yet only exploration could decide whether the condition was operable.

He thought also that exploration was justified, though sparingly, in chronic abdominal cases in which it was believed there might be an organic element, due allowance having been made for constitutional and psychological factors, and other measures tried without success. As for contraindications, exploration of the "chronic abdomen" *per se* was far too frequently regarded as justifiable. Many chronic stomach cases no more justified surgery, even though the physician could not relieve them, than did common headaches or backaches. Many cases of pain in the iliac fossa were allowed to go to unjustifiable operation. It had to be remembered, on the other hand, that again and again an exploratory laparotomy revealed some quite unexpected and quite simple thing, such as an inflamed appendix, when something much worse had been expected, and therein it justified itself. Perhaps in no situation was one more forcibly reminded of the Hippocratic aphorism, "Life is short, the art of healing is long, experience fallacious, judgement difficult." It behoved the surgically minded to be medically thoughtful, and the medically minded to be surgically thoughtful.

Mr. ZACHARY COPE considered that it was justifiable to explore the abdomen or any other part of the body only when every other faculty or means of diagnosis had been exhausted. Disease showed itself in four ways: by anatomical alteration, physiological perversion, general depreciation, and pain. Pain was also a physiological perversion, but it was so characteristic a feature of many diseases of the abdomen, and often the only symptom, as to merit a separate category. Sometimes the diagnostician had only the symptom of pain to help him. If pain persisted in the abdomen in one spot and with increasing intensity, and if it had certain referred areas which were constant, and which suggested that some part of the nervous system was irritated, then it might be justifiable to open the abdomen, but the occasions for so doing were very few. When all four of these signs were present, as in hydronephrosis, there was no doubt whatever—one had the diagnosis. But there were many cases in which only one or two of the signs existed, and exploration seemed to be called for. Operability, again, was a delicate point. There were many cases in which it was hardly justifiable to open, and yet one never knew when one might be able to do something for the patient. It was impossible in many cases to distinguish between pneumococcal peritonitis, salpingitis, and appendicitis. If the indications were clear he would not open in the case of the first two, but would open in the case of the third. When it was not possible to distinguish between them he thought it justifiable to explore.

Dr. H. H. MILLS, speaking as a general physician, had come to the conclusion that there were two areas of the abdomen in which the diagnosis was almost necessarily uncertain—one the region of the gall-bladder, and the other the pelvic area. In the former category there were undoubtedly cases in which, however carefully one went to work, and whatever accessory means of diagnosis were used, the diagnosis remained uncertain until an exploratory operation was done. With regard to the pelvic area, in view of the misery which followed chronic uterine disease and other conditions, he thought as general physicians they were justified in advising an exploratory incision, and that the results were generally satisfactory. There was one series of cases in which the greatest caution should be observed as regards laparotomy—namely, projectile vomiting occurring with pyloric spasm in infants; this was exceedingly common, but, with the exercise of great patience, it did generally resolve.

Mr. HOWARD STRATFORD spoke of one region in which exploratory operation was, in his opinion, extremely important, and invariably done without undue risk. A few years ago a good deal was published about the serious consequences following empyema, especially of the sphenoidal sinus. The sphenoidal sinus was difficult to explore, but such exploration cleared up the diagnosis, and there was no other way of making certain of it. The antrum of Highmore could be explored with extraordinary ease, and here again the diagnosis was cleared up. This was a realm where exploratory operation was absolutely justifiable.

Mr. WINSBURY WHITE referred to exploratory operations in the urinary tract. It was agreed that in the recent past exploratory operations on the kidney and bladder were of great frequency, and often were entitled to be regarded as sound surgery; but that state of affairs did not exist to-day, for with *x* rays and cystoscopy and pyelography it was very unusual for the surgeon not to be able to come to a definite conclusion one way or the other, though there were still certain kidney cases with no tangible pathology. With regard to the bladder also it was unusual not to be able to say in any primary condition what was the cause of the symptoms, and in general it might be said that by carrying out the proper routine, in both kidney and bladder cases, one was left with no justification nowadays for exploring either of these regions.

Dr. G. M. J. SLOT thought that the consequences of exploratory as of other operations ought to be borne in mind. He believed that a woman, particularly one of middle age, who had had a fairly extensive abdominal operation never had quite the same abdomen afterwards. There was visceroptosis, and also functional symptoms, and the patient was really worse off in the long run than before. One part of the body where exploratory operations were not carried out as frequently as they might be was the chest. The operation he had in mind was simple exploratory puncture with the needle. All would agree that such explorations were perfectly justifiable.

Mr. DONALD ARMOUR, in replying, said that the range of the discussion was far greater than he had anticipated. The question of exploratory operation was, after all, one of degree. The cases in which he had pleaded the justifiability of such operation were those in which exhaustive clinical and laboratory investigation had taken place without arriving at a diagnosis. He was rather sorry to hear Mr. Howard Stratford suggest that the sphenoidal sinus could be explored without danger to the patient. There had been a number of such explorations with dire results. It was necessary only to think of the anatomical relations of the sinus. He agreed that in all exploratory operations a factor to be borne in mind was the psychology

of the patient. There was a type of patient, usually female, who demanded operations. He had known a case in which a woman had submitted herself to as many as thirteen *abdominal* operations. Her mental condition must have been like that of the flagellants of the Middle Ages, who found exquisite pleasure in the scourge. He was reminded of the classic case of the lady in Edinburgh who had an obsession that she had a lizard inside her. She so pestered and bothered the surgeons that at last, to satisfy her, they made a feint of operation. All they did actually was to make a small skin incision, but when she came round they told her they had removed the lizard. "What colour was it?" she asked. They replied that it was green. "Well, then," she said, "you haven't got it; that was another *lizard*."

OPERATIVE CYSTOSCOPY.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society held on June 6th, with the president, Mr. GEOFFREY BATE, in the chair, Mr. F. E. FEILDEN read a paper entitled "Some observations on operative cystoscopy."

Mr. Feilden said that operative cystoscopy, for the most part, could be performed under local anaesthesia, thus avoiding the dangers of a general or spinal anaesthesia. If a local anaesthetic was to be of any value, due regard should be paid to the technique of its administration. Delicacy of touch in urethral instrumentation was of paramount importance. To avoid sepsis trauma must be avoided. In cases of suspected stone in any portion of the urinary tract, the investigation was not complete without an *x*-ray examination of the entire tract. The importance of cystoscopy in the investigation of diseases of the urinary tract could not be overestimated. In Mr. Feilden's opinion the bladder sound had ceased to fulfil any useful purpose, and should be discarded. The operation of choice for the removal of all uncomplicated cases of vesical calculi was litholapaxy, by means of a cystoscopic lithotrite. The bladder was opened too often for the removal of certain foreign bodies which could be removed more easily and judiciously by the transurethral route. A calculus impacted in the intramural portion of the ureter might be released by means of a knife or scissors used through an operating cystoscope. Diathermy was of value in the treatment of a ureterocele or vesical cyst, and was also a most satisfactory method of treatment in cases of benign papillomata of the bladder. The size of the electrode used should vary according to the size of the growth—a large electrode would reduce the number of sittings necessary. Diathermy was also of some value in malignant diseases of the bladder. Mr. Feilden did not recommend the removal, for diagnostic purposes, of a piece of bladder growth through an operating cystoscope. Cystoscopy was a most valuable method of investigation in cases of prostatism. In some cases all the symptoms of prostatic disease were present without enlargement of the gland.

The operation of partial prostatectomy, performed with a Kenneth Walker diathermy punch, was a most satisfactory operation in carefully selected cases, but if employed indiscriminately results were certain to be bad. Compared with a suprapubic or perineal prostatectomy the risks were negligible. In conclusion, Mr. Feilden emphasized that success in prostatic surgery was governed by the knowledge when to operate and the appropriate type of operation to employ.

LOCAL GOVERNMENT REFORM AND VOLUNTARY HOSPITALS IN SCOTLAND.

At the annual general meeting of the Royal Medico-Chirurgical Society of Glasgow, on May 3rd, with the president, Dr. JOSHUA FERGUSON, in the chair, an address was given by Dr. J. PARLANE KINLOCH, Chief Medical Officer, Department of Health for Scotland, on the effect of local government reform on the voluntary hospitals in Scotland.

Dr. Kinloch said he had no cut-and-dried plan to expound, and he invited an interchange of views. At the present time the whole medical organization of the country was in a state of transition. His department was attempting to formulate a comprehensive scheme, and in doing so it was taking steps to consult with the medical profession in the four great centres of Scotland. Any opinions which he might express were not to be taken as final or as having Government sanction; they were simply attempts to visualize the new organization. It was impossible to deal specifically with the hospitals alone, because the whole medical organization of the country must be taken into account.

First of all, with regard to finance, it must be remembered that the whole question of expenditure on health services had been reviewed in 1926 by the Royal Commission on National Health Insurance. We were now spending so much on these services as compared with our trade competitors that there was no case for increasing the contributions by employers, workers, or the Treasury until the whole health administration of Britain had been overhauled. Secondly, with regard to the hospitals, three types of institution had to be considered: (1) the great voluntary hospitals; (2) the public health hospitals; (3) the Poor Law hospitals. Accepting the view of the Insurance Commissioners that the health services must in the meantime be reorganized within the existing financial commitment of the Treasury, it became *obvious that the voluntary hospitals must be maintained* at their present level, and, if possible, expanded, if there was to be an adequate hospital service. This would enable the Government contribution to be used to fill up gaps in the existing hospital service and to round off the hospital system. It had been decided that the Poor Law hospital system should be reformed. Except in a few areas like Glasgow and Govan, the system was inferior in quality, and the hospitals must be brought up to a higher level all over Scotland. The Voluntary Hospitals Liaison Committee had played an important part in securing this reform whereby hospitals could be removed from the Poor Law, could become public health hospitals, and could be reconditioned and re-equipped to the standard of the best modern voluntary hospitals. The Liaison Committee was able to speak with the authority of the Voluntary Hospitals Regional Committees, and to advise the secretary in matters concerning these hospitals. This committee had taken the view that the existing voluntary hospitals could not meet the needs of the country, and they had agreed to Clauses 27 and 28 of the Local Government Act (the clauses empowering *local authorities to provide hospitals* and clinics). This implied co-operation between the voluntary hospitals and the statutory hospitals. By this means the position of the voluntary hospitals was safeguarded.

The Local Government Act laid it down that the local authority must have a complete health scheme for its area, including child welfare, ante-natal, and maternity services, medical inspection of school children and of children of pre-school age; the prevention and treatment of infectious diseases, including tuberculosis and venereal diseases; and the treatment of general diseases in the reconditioned Poor Law hospitals. These services would be augmented in certain directions; for example, it was proposed to provide medical treatment for school children. To deal with these requirements they might increase the number of whole-time medical officers, or incorporate the general practitioners within the public health service; the first proposal was a bad one, in Dr. Kinloch's opinion, and he strongly urged the importance of bringing the general practitioners into the scheme. He wished them to realize that if this was to be attained there must be organized *action by the medical profession itself*.

Co-ordination of Medical Services.

The national health insurance service had not been properly correlated so far with the public health services; until recently they had been dealt with by two different departments of the Scottish Board of Health, but this phase of administration had now been centralized for all time in the new Scottish Health Department. There would never be an adequate system until there was some scheme of extension of medical benefit to dependants, but it must be remembered that there was available for such a purpose an annual sum of only five million pounds. To carry out the scheme properly would require twelve million pounds a year—

a sum which the funds of the national health insurance scheme could not provide. It was proposed, therefore, to apply the whole of the funds at present available to the provision of a general practitioner service, while the whole cost of specialist services would have to be met by the local authorities. Dr. Kinloch suggested that this principle was already being applied in the case of the public health services, so that nothing fundamentally new was involved in the plan. The relation of this scheme to the voluntary hospitals and the medical teaching schools must be such that the medical schools embraced the whole. The teaching of medicine must be developed more on the preventive side. There had been some progress in this direction in connexion with the teaching of midwifery, and Dr. Kinloch referred more particularly to the schemes which had been formulated and advocated by Professor Munro Kerr. He thought there should be no difficulty about developing medical education along these lines, but there must be no hard-and-fast rules about no research work being done in the statutory hospitals, and matters of that kind. The medical curriculum must be modified in some way, though he hesitated to suggest in detail what reforms were required. They must not let the universities and the voluntary hospitals say that they were going to absorb the others; it was to be a joint scheme. It was important to prevent competition between the voluntary and the statutory hospitals; there should be the same staffs for both. Members of the visiting staffs of the voluntary hospitals should be *ex officio* consultants within the statutory hospitals, and the routine consultant work in the statutory hospitals should be undertaken by the assistants from the voluntary hospitals' staffs, acting under the supervision of their own chiefs as consultants. There was not enough money to endow a large staff of specialists. For this reason it was not proposed to interfere with the present status and privileges of the "chiefs" in voluntary hospitals. At present they had a certain say in the admission of patients, and so forth, and it was now proposed to continue this privilege with certain modifications. By a system of allocation of cases the voluntary hospitals would be kept full, the superintendents and the medical officer of health reviewing the waiting list from day to day. The normal mode of admission of patients would be from the central waiting list, but if any particular case was wanted by a surgeon it would go to his wards, and would not appear on the general list. There would thus be a new organization from the centre outwards.

The present referee system must be replaced by one in which local referees were increasingly employed and the regional referees were connected with the consulting teams in the various hospitals. These regional referees would act as a link between the medical officer of health and the voluntary and statutory hospitals on the one hand, and the general practitioners on the other hand. It was essential to put a stop to the present excessive medical certification of disablement; this would be possible only when there was an adequate consulting service.

Hospitals and the Act.

There were three important sections in the new Act relating to hospitals: (*a*) Section 14, giving power to transfer Poor Law hospitals to the public health hospital service; (*b*) Sections 27 and 28, the vital hospital clauses; and (*c*) Section 65, requiring a definite standard of efficiency in the hospital service. The larger public health areas defined by the Local Government Act would permit of more efficient health services within each of these areas, but the most important aim was to secure that the health services of these new and enlarged local authority areas were orientated towards the medical schools. In other words, the whole tendency was to evolve a regional hospital and medical service scheme out of the new local authority medical service scheme. For this purpose Scotland naturally fell into four main areas supplying the four medical teaching schools. From the point of view of the Central Department of Health such a regional system was in process of being developed in connexion with the national health insurance service.

So far as the medical teaching schools were concerned, it would be an easy matter to undertake that the teaching hospitals were supplied with a suitable admixture of cases. If, however, this was regarded as the solution of the teaching problem, then the medical schools must be content to be miniature medical schools. The real solution of the problem was for the medical schools to expand and embrace the statutory hospitals of their areas. Under such an arrangement, and without interference with the management of the voluntary and statutory hospitals, the teachers in the teaching hospitals would have access for teaching purposes to the statutory hospitals, and their assistants would largely be employed in providing the actual specialist medical and surgical services required by the local authority hospitals. Under such an arrangement there would be a co-partnership of the university authorities, the authorities of the voluntary hospitals, and the authorities of the statutory hospitals.

In the discussion which ensued Dr. A. S. M. MACGREGOR expressed the belief that it would be a long time before all the schemes which were contemplated came into operation; there must be gradual progress and evolution. He welcomed Dr. Kinloch's statement that there was to be an extension of benefit to the dependants of insured persons at an early date, for, in his opinion, no proper scheme of medical treatment could be made without this. He agreed with Dr. Kinloch that the interests of the voluntary hospitals as medical training schools must be paramount. The great benefit of the new proposals was that they removed the Poor Law system and opened up a whole field of disease to be dealt with in an organized way.

Professor E. P. CATHCART commented on the difficulty of altering the medical curriculum as at present constituted; he did not think it possible to do so without lengthening it.

Professor J. H. TEACHER cordially agreed with Dr. Kinloch's proposals to improve the facilities for teaching. He pointed out that in Glasgow an important reform of the curriculum in harmony with the views of Dr. Kinloch was already in force—namely, the schemes which had been initiated by Professor Munro Kerr in connexion with the teaching of midwifery, and which had led to important alterations in the curriculum as a whole. The scheme would economize the student's time, and give him access to certain subjects in a way which would emphasize the preventive side of medicine.

Dr. J. B. MILLER considered that the proposals outlined by Dr. Kinloch were a charter for the general practitioner of the future. The National Health Insurance Act was ostensibly an effort to raise the health of the people, and the bringing in of dependants was a necessary development of this idea.

Dr. J. FERGUSON SMITH said that in his view not the least important part of the work of the voluntary hospitals was done in the out-patient departments, and that no scheme which failed to realize this was likely to be satisfactory. He wondered what provision would be made for the support of the younger consultants. It was probably true that there were already twice as many men and women required to do the work of the hospitals as could make a reasonable living from the practice of their specialties. If the new statutory hospitals drew off any appreciable fraction of those patients who now obtained special treatment in private the position would be aggravated.

Dr. PARLANE KINLOCH, replying, said that the extension of medical benefit to dependants was still non-existent. If funds were diverted to specialist services there would be nothing available for the provision of benefits for dependants; this was the reason for bringing in the local authority. With regard to the management of the voluntary hospitals he wished to make it clear that what was intended was that the voluntary hospitals should control their own affairs, and that the statutory hospitals should be managed by the local authority. The consultants would remain in the same relation to the voluntary hospitals as at present, and would, in addition, come on the staffs of the statutory hospitals, where they would be working under the conditions existing there. In the future the supply of consultants would probably be increasingly regulated; they would graduate through the voluntary and statutory hospitals to junior teaching and research posts before admission to consultant rank.

Reviews.

MENTAL DEFICIENCY.

FOLLOWING appositely upon the publication of three parts of the Report of the Joint Committee of the Board of Education and Board of Control on Mental Deficiency, comes a fifth edition[1] of Dr. A. F. TREDGOLD's well-known and standard work on that subject and under that title. The report of the committee was described and commented upon in a leading article in the *Journal* of April 27th last (p. 775), and the fourth edition of Dr. Tredgold's work was reviewed on February 17th, 1923 (p. 291). The preface to the new edition reminds us that the book was first published in 1908, and that "during this twenty-one years there has been a markedly increased recognition of the importance of the subject with which it deals both by the medical profession and by the educated laity." It was the subject chosen for consideration by the Section of Medical Sociology at the Annual Meeting of the British Medical Association held at Portsmouth in July, 1923, and a reference to the full and interesting report of the discussion which then took place (*British Medical Journal*, August 11th, 1923, p. 219) may be profitable. The yearly conferences under the auspices of the Central Association for Mental Welfare are further evidence of a deepened and more intelligent concern with the social, medical, and educational problems connected with mental deficiency. Its nature, its varieties, its exact effects, have of recent years come to be more fully understood and appreciated, though it is still a subject on which medical men of some eminence, as well as some laymen, permit themselves to make public dogmatic statements based upon obsolete ideas and statistics that are long out of date. Part IV of the Report of the Joint Committee consists of a description of a detailed investigation made by Dr. E. O. Lewis and some colleagues under his direction in six areas in England and Wales, chosen as representative, and sets out the results and conclusions so arrived at. These should be studied in the report itself, for no summary can do justice to their interest and value, but their importance is indicated by the findings that the incidence figure of mental deficiency is not less than 8.5 per 1,000 population, that this is approximately twice as great as had previously been imagined, and that there can be no doubt that the number of mentally deficient persons is steadily increasing. Parliament has recognized the national importance of the matter, and the need for communal action, in the Mental Deficiency Acts of 1913 and 1927, but effective administration of the law is woefully lacking.

Facts like these make a book such as Dr. Tredgold's all the more necessary and valuable, and the latest figures and statistical tables and the most recent results of authentic research are embodied in the new edition. The general plan of the volume remains the same as in previous editions, but every chapter has undergone a complete revision. Some chapters have been entirely rewritten and their order has been rearranged. Material alterations will be found on a large proportion of the pages, and these have been very carefully and judiciously made. A number of new illustrations have been added. These changes have enhanced the value of a book which was already indispensable to those, whether medical or lay, who wish to have authoritative information and reliable opinions and judgement on the subject with which it deals. It is a book to be read, as well as a work of reference which it would be wise always to have at hand. It is very complete in its survey. The nature and definition of mental deficiency, its incidence, causation, classification, pathology, and psychology are dealt with. The physical characteristics of the different kinds of amentia are described, as well as the diagnosis, prognosis, and treatment of its clinical varieties, and their relation to other forms of mental disease and disorder. Moral deficiency, including the psychological basis of misconduct and the relation of mental deficiency to recidivism, is discussed in an important chapter. The law concerning amentia is set out, and various social questions relating to the education, employment, and general supervision of defectives are adequately considered. The final pages in the section on remedial measures, many of which are new in this edition, may be commended to the special attention of medical men, parliamentarians, and social and educational workers. They embody relatively recent conceptions of the biological causes of mental deficiency, and of its practical and genetic relationship to general mental dullness and instability, and emphasize the bearing of these things upon the questions of sterilization, segregation, and supervision, all of which are likely to be again under discussion in the early future.

In connexion with our review of this standard work we should like to draw attention to an article in the *British Journal of Medical Psychology* (vol. viii, Part IV, 1928) by Dr. Henry Harris on "Mental deficiency and maladjustment." It constitutes, in relatively small compass, a wide survey of such defect and maladjustment from the biological, psychological, and social aspects, which readers will find of great value and suggestiveness.

[1] *Mental Deficiency (Amentia).* By A. F. Tredgold, M.D.Durh., F.R.C.P.Lond., F.R.S.Ed. Fifth edition, largely rewritten. London: Baillière, Tindall and Cox. 1929. (Demy 8vo, pp. xvi – 535; 35 plates. 25s. net.)

ANATOMY FOR STUDENTS.

IN *Surface Anatomy*,[2] by Professor ARTHUR ROBINSON and Dr. E. B. JAMIESON, the subject is treated without reference to its clinical implications, the book being primarily intended for students whose work still lies in the dissecting room. Students in their final years, for whom the subject has a more practical importance, must therefore supplement the information given with clinical details obtained elsewhere. The book, however, is far from being concerned solely with surface form or even with the immediately underlying structures on which the form depends. Although perhaps the most obvious departure from the strict letter of the title is to be found in the account of the segmental nerve supply of the skin, many other instances might be given of the broad sense in which the authors interpret the subject.

The text is divided into seven sections, a separate section being allotted to the back. Each section is in turn subdivided into subsections, the structures being considered more systematically than topographically, under such headings as muscles, nerves, arteries, etc. The work is characterized by the thoroughness and accuracy which we associate with such experienced anatomists, and offers little scope for criticism. We note, however, despite the fact that the volume runs to 175 pages, a number of omissions which perhaps might in a future edition receive attention, particularly as several of them have a practical value. No mention is made, for example, of the levator cushion at the orifice of the Eustachian tube, or of the important connexion of the facial vein with the veins in the orbit. The only reference, again, to the important group of lymph glands which lies along the course of the recurrent laryngeal nerve is the statement that "small scattered glands lie on the front and sides of the trachea and larynx." A few of the illustrations, we regret to say, fail to reach the high standard to which we are accustomed in modern textbooks, and particularly in those published by the Oxford University Press. In Figure 21 the terminal part of the duodenum appears to pass in front of the transverse colon; in Figure 26 the continuity of the pulmonary artery with the infundibulum of the right ventricle is not apparent; in Figure 35 the cervical enlargement is shown too low and too localized; a carelessness is shown in the delineation of the bones of the foot in Figures 30 and 31. These are, however, minor blemishes; a more serious fault, in our opinion, lies in the dissociation of surface anatomy from applied anatomy and skiagraphy, whereby the subject is robbed of its main interest and value.

In Part IX of *Baillière's Synthetic Anatomy*[3] Dr. CHEESMAN continues his series of anatomical drawings on transparent sheets, his purpose being, as is probably now

[2] *Surface Anatomy.* By Arthur Robinson, M.D., F.R.C.S., and E. B. Jamieson, M.D. Oxford Medical Publications. London: Milford, Oxford University Press. 1923. (Roy. 8vo, pp. vii + 175; 12 figures. 15s. net.)

[3] *Baillière's Synthetic Anatomy.* By J. E. Cheesman. Parts IX and IXA. Baillière, Tindall and Cox. 1923. (7½ × 9; each part contains 12 plates and costs 2s. 6d.)

well known, to assist the student to reconstruct the various regions of the body by the superposition of drawings made on successive planes. In the part under notice Dr. Cheesman supplies drawings of the head and neck, while in Part IXA he provides a supplement in the form of drawings of the pterygo-maxillary region, on an enlarged scale. Owing to the multiplicity of the structures therein, and still more to the irregularity of the numerous planes in which they lie, the head and neck present difficulties sufficient to daunt anyone with less patience or skill than Dr. Cheesman. It is not surprising, therefore, that he has not altogether succeeded in maintaining in this volume the standard of his previous work. Nevertheless, with the exception of Figure 8 in Part IX, where the vertebral column appears to us to be unduly rotated, the figures are, generally speaking, both accurate and clear, and we congratulate Dr. Cheesman on the satisfactory completion of another chapter of his original and ingenious work.

FRACTURES.

THE appearance of a second edition of *Fractures and Dislocations*[4] by PHILIP WILSON and W. A. COCHRANE in four years shows that the merits of the book which we reviewed in our issue of May 16th, 1925 (p. 928) have been appreciated. Since then Mr. Cochrane's experience in Edinburgh has increased and the second edition is less an exposition of American practice than the first. Our good opinion of this book remains unaltered, and we only regret that we cannot put on record a greater advance in this country in the direction of the organization of fracture departments of hospitals on the Massachusetts model, to which the treatment of fractures in Boston owes so much. This revised edition contains the same number of pages as the first, but there are fifty-one more illustrations.

The recent articles and letters in the *British Medical Journal* on the treatment of Colles's fracture led us to refer to the section on this subject in Messrs. Wilson and Cochrane's book. As Mr. Cochrane recently stated in our columns, he considers that a frequent complication of this fracture of the radius is a partial luxation of the lower end of the ulna. We have turned to the new edition in the hope of finding a more detailed and exact definition of his meaning, but we are still uncertain as to what is meant by luxation of the ulna in this connexion. The unbroken ulna might have lost its normal relation with the triangular fibro-cartilage and carpus; in which case it would be more correct to say that the luxation was one of the carpus. Or, as nearly always happens in this fracture, the lower ends of the ulna and radius might have lost their normal relative positions, but in such a case it is the fractured radius which is luxated and not the ulna. Any abnormality in the position of the lower end of the ulna as regards the carpus and lower end of the radius should surely be described as a luxation of the fractured bone, and not as one of the uninjured bone of which the relations with the rest of the forearm are undisturbed. The point is one of more than mere words and names. The question involved is one of principle, on which much depends. The attention of the student should not be diverted to a supposed luxation of the ulna, when the need of the moment is the restoration of the lower end of the radius to its normal relationship with the rest of the forearm, of which the lower end of the ulna is but a part.

THYROID SECRETION.

Thyroxine,[5] by Professor E. C. KENDALL, is the latest contribution to the American Chemical Society Monograph Series. Anything written by this author on this subject is of great interest and importance, and the volume constitutes an authoritative summary of our present knowledge concerning the chemistry and physiology of thyroid secretion. The chemical section is, of course, of particular interest, and a full account is given of the author's own work, which laid down the foundations of our knowledge of this subject, and of the work of Harington, which solved the problem of the chemical nature of thyroxine, and led to its synthesis. The physiology of the thyroid is dealt with fully, and a very great amount of information has been collected; but this section would be made clearer by more careful arrangement of the subject-matter.

The author, in a brief discussion of the clinical aspects of his subject, remarks that many of the problems of greatest clinical interest are undecided. Whether the toxic effects in exophthalmic goitre are due to an excess of normal secretion or to the formation of an abnormal secretion is considered to be uncertain. In this connexion we note with interest that the author believes that at least three kinds of organic iodine compounds are present in the normal gland. The bulk of the iodine is in a form which is physiologically inert. The proportion present as thyroxine is always less than 15 per cent. of the total iodine content. Some glands which contain no thyroxine are nevertheless physiologically active, and therefore Kendall believes that thyroxine is an intermediate product, and that before it exerts a physiological action it passes into some slightly altered form which he terms "active thyroxine." The beneficial action produced by minute doses of iodine in exophthalmic goitre is described, but it is concluded that at present we do not know how this comes about.

The letterpress comprises only 230 pages, and is followed by a bibliography of 541 references. These figures indicate that all discussion has been reduced to a minimum, and the volume is chiefly occupied by the description of the results that have been obtained. The reader is, however, helped greatly by short summaries at the end of each chapter, in which the author states what appear to him to be the outstanding conclusions that may be drawn from the evidence available. The fact that the author is a leading authority on his subject makes these summaries of particular interest.

SURGERY IN THE TROPICS.

IT is a pleasure to welcome two such books as *Tropical Surgery and Surgical Pathology*,[6] by Major K. K. CHATTERJI, and *Surgery in the Tropics*,[7] by Sir FRANK P. CONNOR, for they are certainly needed, though some might not realize it. Doubtless, a good surgeon will do good work anywhere, but his best cannot be achieved without a working knowledge of local diseases and conditions, and it is just such information that these books convey, as far as writings can do. An experienced surgeon will appreciate this proviso, while the tyro may safely be guided by the rules and methods set forth.

In the introduction to *Tropical Surgery* Major Chatterji mentions that he is handicapped by writing in a foreign language; we could wish that this same language held no greater handicap for many of those who learnt it at their mother's knee, for the clarity of the exposition alone makes the book worth reading. Definite and minute instructions are given for various operative procedures as well as general measures. Some notes upon blood transfusion and upon protein shock might have found a place, and it was with surprise that we failed to find climatic bubo in the index. The book deals more particularly with the graver surgical conditions, major operations, and the scientific aspect of disease, so that it will be of more use to the experienced surgeon with every hospital facility found in the big towns, and to the student in his final year, than to the isolated practitioner endeavouring to carry on the art of healing to the best of his ability and circumstance. The volume includes a foreword by Sir Havelock Charles and a useful bibliography; it is profusely illustrated, and numerous coloured plates are given. Indeed, the author and publishers are to be congratulated upon the

[5] *Thyroxine.* By Edward C. Kendall, M.S., Ph.D., D.Sc. American Chemical Society Monograph Series. New York: The Chemical Catalog Company, Inc. 1929. (Med. 8vo, pp. 265; 39 figures. 5.50 dollars.)

[6] *Tropical Surgery and Surgical Pathology.* By Karuna K. Chatterji, F.R.C.S.I., Major I.T.F. Medical Corps. With a foreword by Major-General Sir R. Havelock Charles, G.C.V.O., K.C.S.I., etc. London: J. Bale, Sons and Danielsson, Ltd. (Demy 8vo, pp. xxx + 244; 131 figures. 16s. net.)

[7] *Surgery in the Tropics.* By Sir Frank Powell Connor, D.S.O., F.R.C.S. Churchill's Empire Series. London: J. and A. Churchill. 1929. (5¼ × 8¼, pp. ix + 293. 99 figures. 12s. 6d.)

production of such a well turned out book at a reasonable price.

In *Surgery in the Tropics* Sir Frank Connor has achieved a most readable and helpful book of a very convenient size, and his method of discussing the surgical possibilities of most tropical diseases is at once stimulating and valuable. He avoids too great detail, yet a little more might be appreciated; for example, the points for and against the closure of a caecostomy, together with the chances of bowel stenosis and failure, might well be discussed. We note the faint praise accorded to lymphangioplasty, but scarcely expected even so much. The book is well illustrated and has a useful appendix, and from first to last the subject is covered in a most practical manner, so that this work should find a prominent place in the library of every practitioner in the tropics. We look forward to seeing a second edition in the near future.

DARWIN AND DARWINISM.

It might seem that at this time of day there could be no possible need to write another life of Charles Darwin. However, during the last five-and-twenty years there has been considerable criticism, not unmixed with misrepresentation, of Darwin and Darwinism, and HENSHAW WARD'S *Charles Darwin*[1] may therefore be regarded as timely. It is a well-written narrative, designed ostensibly to display what the author holds to be the chief meaning of Darwin's career, "that the result of his fifty years of observing nature was to teach the world not to rely on speculation." Some may consider that this fact had already been driven home by Bacon, Newton, Harvey, Hunter, and others, but there is no doubt that Darwin affords a brilliant example of the value of accurate observation, and this aspect of his life is emphasized over and over again in the author's book. But considerable space is also devoted to an explanation of Darwin's relation to the various theories on the nature of species which were current at the time, and as the facts are stated with much impartiality this may be considered to be the most interesting part of the book. The Mosaic idea of the stability of species prevailed generally, although some scientists—Lyell, for example—recognized that variations due to natural causes might arise within a species and cause structural resemblances to other species, simulating a genetic relationship. Buffon went so far as to admit that the resemblances were so striking in many cases that the theory of a genetic relationship would quite well serve as an adequate explanation. But there was an alternative, and this he adopted. "It is certain," he writes, "from revelation, that the original pair of each species issued full-formed from the hands of the Creator." It has been suggested that this plain statement was mere sarcasm; if this is so it becomes impossible to accept any of Buffon's statements with a feeling of security. Lamarck went further: he believed in the mutability of species as adumbrated by Buffon, but he also made an original contribution to the problem in the shape of a theory of the evolutionary process. He supposed—without adducing any considerable body of facts in support of his supposition—that the needs of animals entailed structural alterations in response to alterations in the environment; thus, since circumstances rendered it necessary for the giraffe to reach up to the trees for food, the animal's neck would become gradually stretched in the effort, and the resulting elongation would be transmitted to the offspring. If such reasoning were all that could be said in support of the theory of evolution, one would fain go back to the old Mosaic doctrine of creation, which at least had the merit of being a fine conception. It was at this stage that Darwin began his indefatigable labours and—with a hint, perhaps, from Malthus—developed his theory of evolution through variation and natural selection. The theory has the ring of truth in it, and it has altered and ennobled our whole conception of life. While admitting its truth, no one is called upon to admit that it is the whole truth; and Darwin himself has stated that "of course, my natural selection is not the only factor in evolution"—a circumstance which is sometimes forgotten in discussing Darwinism. The new theory was bound to come into collision with stereotyped beliefs. Hence the absurd meeting at Oxford—reminiscent in a minor degree of the final meeting of the Stanislow Society described in Bret Harte's poem—at which the bishop proposed to "smash" Darwin, and Hooker claimed to have "smashed" the bishop. Darwin would derive small satisfaction from sentiments of this kind; "the theological view of the question," he said, "is always painful to me. I am bewildered."

NOTES ON BOOKS.

WHEN in 1927 (July 9th, p. 61) we reviewed the first edition of Dr. SAMSON WRIGHT'S *Applied Physiology*, we commented on the amount and value of the information it contained and the attractive manner in which it was presented. The second edition,[2] recently published, appears to include the whole of the material in the first, revised and brought up to date, and a considerable number of sections dealing with fresh subjects. The work fulfils the needs of the practitioner seeking to correlate his clinical work with its underlying physiological principles, no less than those of the advanced student reading for higher medical degrees and diplomas.

In Fractures of the Upper End of the Humerus[10] Dr. GIAN CARLO PERACCHIA describes the normal anatomy of the parts concerned and the pathology of fractures in the same region. The work is well illustrated with radiograms, photographs, and drawings, and the results of treatment are set forth. While he considers that bloodless treatment should be the rule for these injuries, he recognizes and describes cases in which open operation and nailing or plating must be necessary. The book is well got up, and will be useful to readers of Italian, although it contains no startling new departure.

In *Nouveau Précis de Bactériologie*[11] Drs. DELATER and GRANDCLAUDE give us the course of instruction in bacteriology held in the dental schools of Paris. It consists of ten lectures and eleven practical classes; the latter part is profusely illustrated with coloured pictures which may well prove helpful to the student in remembering the cultural characteristics of the commoner organisms. It provides a clear and concise elementary introduction to the subject, but, covering as it does a wide ground, it is disappointingly brief in its treatment of the bacteriology of the mouth and its application to dental pathology: more work has been done on this subject than might be supposed from the nine pages here devoted to it.

[2] *Applied Physiology.* By Samson Wright, M.D., M.R.C.P. With introduction by Noble Vincent, M.D., LL.D., D.Sc., F.R.S.Ed. and Canada. Second edition. London: Milford, Oxford University Press. (Demy 8vo, pp. xxii + 510; 178 figures. 12s. net.)

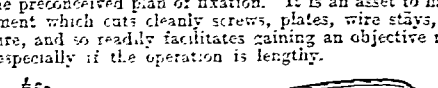
PREPARATIONS AND APPLIANCES.

STEEL-CUTTING FORCEPS.

MAJOR MAURICE SINCLAIR, C.M.G., R.A.M.C.(ret.), W.1, writes: The very powerful and compact steel-cutter here illustrated divides (with limitations) all metals from steel plates to silver wire, and does so with a minimum of muscular effort. It is useful to have such an instrument at hand while undertaking bone operations, since unfortunately every fracture does not fall into the preconceived plan of fixation. It is an asset to have an instrument which cuts cleanly screws, plates, wire stays, bolts, and wire, and so readily facilitates gaining an objective neatly, more especially if the operation is lengthy.

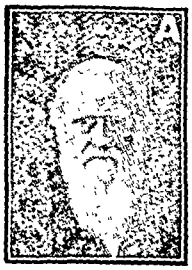


The blades are set at an angle to the handles in order to allow the actuating hand, when cutting within the tissues, to be placed out of the line of vision. After having wired the fragments of bone together the cutter readily allows one, in a deep wound, to see, and at the same time to cut off, the surplus twisted wire with a single effortless movement, and, moreover, without ever having to resort (as one often has to do with a less powerful instrument) to those rocking and flexing movements to break off the wire; these only tend to loosen the hold, and may be prejudicial to an otherwise good mechanical result.

The instrument is made for me by Down Brothers, Limited, London.

CHARLES DARWIN'S HOME.

OPENING CEREMONY AT DOWN HOUSE.



AT the meeting of the British Association in 1927, Sir Arthur Keith, as President, made an appeal for the preservation of Down House, in the county of Kent, as a memorial to Charles Darwin, who lived there from September 14th, 1842, until his death on April 19th, 1882. As recorded in our issue of September 10th, 1927 (p. 464), an immediate response to this appeal came from Mr. George Buckston Browne, F.R.C.S., F.S.A., who undertook to make himself wholly responsible for buying the estate and establishing a fund for its upkeep, in order to permit future generations to visit Darwin's home. Having acquired the property, Mr. Buckston Browne offered to transfer its possession to the British Association under the most liberal conditions, and with an endowment for its maintenance for all time. His desire was that Down House should be regarded as a gift to the nation, and that the British Association should use the building and grounds for the benefit of science. The General Committee of the Association thereupon authorized its President to accept with gratitude this munificent offer.

During the past six months Mr. Buckston Browne has fully restored the whole building and brought back the ground floor rooms—particularly the "old study" in which the *Origin of Species* was written—as far as possible to their condition in Darwin's time. Members of the Darwin family and other friends have generously co-operated in the work of restoration in order that the furniture and decoration of the lower rooms of the house might call to mind the surroundings in which Darwin thought and wrote for the greater part of his working life. The donor has devoted himself also to getting together the nucleus of a Darwin Collection for Down, and commissioned Mr. John Collier to paint replicas of his portraits of Darwin and Huxley to be hung there.

DOWN HOUSE FROM THE SOUTH.

The formal opening of Down House as a public memorial to the great naturalist took place on the afternoon of Friday, June 7th, when a large and distinguished company attended a garden party given by the President (Sir William Bragg) and officers of the British Association in the grounds of this secluded country house on the chalky Kentish uplands. The ceremony was held on the lawn under the presidency of Sir WILLIAM BRAGG, at whose invitation Mr. BUCKSTON BROWNE formally presented the house into the keeping of the British Association, and gave a brief address. Darwin, he said, influenced the mind not only of his own generation, but of the whole world for all time. Like Shakespeare, he was so great that he required no monument, but it might be permitted to them to preserve and keep sacred the house that sheltered Darwin and the things he handled and the grounds he walked on. This it had been his great privilege to be allowed to accomplish, with the willing assistance of Major Leonard Darwin (only surviving son of Charles Darwin) and other members of the family.

Sir WILLIAM BRAGG, in accepting the property as a national memorial, expressed the gratitude and appreciation of the officers of the British Association, not only for the gift itself, but also for the immense pains taken by Mr. Buckston Browne in supervising personally the work of restoration.

Sir ARTHUR KEITH then, at the President's request, declared Down House open to the public. They were assembled, he said, at a place which enshrined the personality of a great man, whom they were justly proud to claim as English through and through. Their distant successors would be proud of it, not so much perhaps on account of the books which were composed and written within its walls, but rather because of the personality of the man who wrote them—a man both good and great. It was right to stress this personal aspect of Darwin's life: he was an English gentleman, gentle and modest almost beyond parallel, living and loved in his home as few men had been; thoughtful for his community, just and charitable, even to those who sought to brand him as an enemy of mankind. Unwittingly Darwin had made these few acres of upland an international possession; in these grounds and within these walls were slowly hammered out new doctrines, which had penetrated to the ends of the earth, giving humanity a new interpretation of living things and its relationship to them. In entrusting his gift to the British Association Mr. Buckston Browne had made no stipulations, for he did not wish Darwin's home to be bound by the dead hand of the law. He had expressed, however, three personal wishes: that the house and grounds should be maintained as nearly as possible as Darwin knew them; that visitors, irrespective of nationality or creed, should be given free access to the public rooms and grounds; and that the officers of the British Association should use Down House to advance the cause of science in such manner as they thought best. In conclusion, Sir Arthur Keith recalled the profound impression made upon him by his first visit to that place, when he obtained a background for a mental picture in which the living Darwin moved, experimented, and thought. It seemed to him that a student would never know Darwin until he knew Down. Science could not be separated from personality. In making this place a national heritage they were acknowledging that sentiment had a place in science—not in the work of the laboratory, but in the heart of the scientific worker. They were not dedicating a monument to Darwin's memory, for he needed none; his works would outlast anything they could build in stone. They were giving way to a sentiment, an impulse, which was deeply implanted in human nature.

Dr. R. ANTHONY, professor of comparative anatomy at the National Museum of Natural History in Paris, briefly conveyed the congratulations of French science; and Dr. JOSEPH LEIDY, speaking on behalf of American science, recalled that Darwin was elected a corresponding member of the Philadelphia Academy of Natural Science immediately on receipt of the first edition of the *Origin of Species* in America. Among the congratulatory messages read by the President was one from Professor Henry Fairfield Osborn, President of the American Association for the Advancement of Science. A sympathetic article by Professor Osborn on the restoration of Darwin's House at Down appears in the issue of *Science* for May 24th.

An important part of the afternoon's proceedings was the pious pilgrimage made by every visitor to the kitchen garden and experimental greenhouses, and to the plantation with its "sand-walk," where Darwin paced up and down every day swinging his iron-shod stick and meditating on his work.

Charles Darwin was the son and grandson of medical men, and the estate at Down was purchased for him by his father, Dr. Robert Waring Darwin of Shrewsbury. He himself studied medicine for a time, and his third son and biographer, Sir Francis Darwin, was a graduate in medicine. A member of our profession made the first public appeal for the preservation of Down House, and another has with splendid generosity carried through the project. It was appropriate, therefore, that at the open-

ing ceremony the principal speeches were made by Sir Arthur Keith and Mr. Buckston Browne, and that the company included Sir John Rose Bradford, President, and Sir Thomas Barlow, Past-President, of the Royal College of Physicians of London, and Sir John Bland-Sutton, Past-President of the Royal College of Surgeons of England. In conclusion, we may note that Mr. Buckston Browne represents the fifth medical generation of his family, the first of the line having been Dr. Theophilus Browne of Derby, who was a fellow townsman and contemporary of Dr. Erasmus Darwin, grandfather of Charles Darwin.

EARLY TREATMENT OF SYPHILIS.

THE most recently issued report (No. 132) of the Medical Research Council relates to the treatment of syphilis, and, as we indicated last week when briefly announcing its publication, Colonel L. W. Harrison has directed attention to some points of great practical interest. The importance of commencing the treatment of syphilis as soon as possible has always been emphasized, but there has long been a suspicion that such early treatment may at times be unexpectedly ineffective as regards the prevention of the later sequels, and a definition of the limits of "earliness" is obviously desirable. Then, again, individual idiosyncrasy must be recognized as a by no means negligible factor, and renders it difficult to foretell how any particular patient will respond to treatment. The diversity of therapeutic methods in common use is an obvious indication that much remains to be learnt as regards the most suitable procedure, for, although more than 260,000 cases of syphilis have now been dealt with in treatment centres in England and Wales, very little attempt has been made to classify the results in relation to the kind of treatment adopted.

Colonel Harrison has surveyed the clinical records of all male cases of syphilis seen for the first time in the St. Thomas's Hospital venereal diseases department from January, 1920, to the end of March, 1926, and kept under observation till the end of June, 1927. His report consists of two parts. The first of these, which occupies the bulk of the booklet, reviews the results of treatment. Thus, different arsenobenzol compounds are compared as regards their effect on the Wassermann reaction; mercury is contrasted with bismuth in respect of its adjuvant effect; the responses of patients in different stages of syphilis to a single and to two courses of treatment are compared; and an attempt is made to assess the prognostic value which can be attached in early cases of this disease to the serological response to the first two courses of treatment. The incidence of relapses is considered, with special relation to involvement of the central nervous system, and the necessity of examining the cerebro-spinal fluid. Mention is made of the apparent possibility in a few cases of eradicating syphilis with very little treatment. In the short second part of the report Colonel Harrison deals with the sites of primary syphilitic lesions, and the occupations and ages of patients. It appears that extragenital syphilis is less common in Great Britain than was previously suspected on the basis of returns received from certain Continental countries.

Comparison of Therapeutic Methods.

Colonel Harrison comments on the regrettable differences of practice as regards treating syphilis which prevail at present; he suggests that it is greatly to be desired that those who are dealing with large numbers of cases should endeavour to take stock of their results and support their opinions by statistical evidence. He remarks that the result of treatment depends in very great measure upon the stage of the disease in which it is started, and that, consequently, different lines of treatment can only be legitimately compared by studying their effects on patients whose infections are within much the same narrow limits of duration. It is also necessary, in his opinion, to take into account the time over which a given total dosage has been spread, as well as the sizes of individual doses. To reach any reliable conclusion as to the requirements for eradicating syphilis from persons in different stages, it is essential to study the results of administering different total dosages in approximately the same time intervals to patients in much the same stages of the disease.

In his survey at St. Thomas's Hospital the following rules were observed in classification. A course of treatment must consist of not less than 5 grams of arsenobenzol compounds (except in the case of silver salvarsan) in conjunction with a minimum of 5 grams of mercury or 2 grams of bismuth, the course being continued for not more than four months. To qualify for admission to the category of "cases treated with two regular courses" the patients had to have received such a first course as defined, and have started the second course within three months of the end of the first course, completing it not more than four months later. To estimate the immediate effect of a course of treatment it was held essential that the blood tests should have been performed within one month of completion of the course. The Wassermann test method employed was No. 1 in the Medical Research Council's Special Report (No. 14).

Comparison in this way of different arsenobenzol brands, as judged by the effect produced by one course, led Colonel Harrison to the conclusion that no one brand was outstandingly better than any other. So far as can be judged by the serological effect of a single course of an arsenobenzol compound with mercury, as compared with one in which the compound was associated with bismuth (in an admittedly small number of sero-positive primary and early secondary cases) the adjuvant effect of the bismuth compound employed did not appear to be greater than that of mercury. The possibility is recognized, however, that the best bismuth preparation may not have been used; it is admitted also that bismuth therapy has distinct advantages over mercurial treatment in respect of tolerability.

Prognostic Considerations.

Comparison of the response to one and to two courses of treatment in different stages of syphilis is indicated by two tables. The effect of treatment is shown to diminish proportionately as the disease increases in duration, and thus the value of beginning remedial measures early is clearly indicated. Spacing out the injections of arsenobenzol compounds in small groups of doses separated by intervals each of one month seems to be a useful procedure; no jaundice or dermatitis resulted in Colonel Harrison's series. It seems probable, however, that no particular combination of dosage and intervals will ensure 100 per cent. of negative reactions in cases which have already become serologically positive. Patients who did not respond to the first course of treatment continued positive in greater numbers than those in which the reactions had been reduced by treatment to weak positive or negative. The after-histories of the cases left with weak positive reactions after the first course did not appear to be worse than those of cases which ended the first course with negative or weak Wassermann reactions.

Colonel Harrison draws the important conclusion that the more or less unsatisfactory after-histories of a number of those patients who were negative at the end of the first course and received regular treatment subsequently show that even the attainment of a negative reaction by such a first course is by no means a guarantee of its maintenance, even under regular treatment. Still, the fact remained clear that the outlook for primary cases treated while still sero-negative appeared to be distinctly better than in the case of those which were sero-positive at the beginning of treatment, even when these became negative at the end of a single course. Another valuable point noted is that the incidence of recurrent chancre points to the importance of local treatment of all primary sores.

Colonel Harrison concludes: (1) that in sero-negative primary cases a completely satisfactory percentage of cures cannot be expected from less than two full courses as defined by him; (2) in sero-positive primary and early secondary cases even three full courses do not afford a sufficiently satisfactory percentage of permanently negative reactions; (3) most relapses in the early stages occur in the first year, only a very small proportion developing after the second year; (4) while in some cases a very small amount of treatment appeared to have sufficed for the eradication of the disease, in other cases considerable amounts failed though administered regularly.

British Medical Journal.

SATURDAY, JUNE 15TH, 1929.

THE MEDICAL PROFESSION IN PARLIAMENT.

WITH the declaration of the poll for the Scottish Universities on Monday last, it has become possible to review completely and accurately the position of the profession of medicine in the new Parliament. In the House of Lords Lord Dawson has received the very welcome reinforcement of Lord Moynihan. Recent experience has shown that knowledge, reasonableness, and persistency combined can produce in that House great effect for the public good, even though the number of the advocates be small, and it would be difficult to imagine a more persuasive union of those qualities than in the two medical peers.

There are now eighteen registered medical practitioners who are members of the new House of Commons, as against thirteen in the old. They were all elected, of course, primarily as politicians, and all save one as party politicians. Dr. Graham Little, whom we may congratulate on the decisive nature of the result in his case, sits as an independent member for London University. We may be permitted also to endorse his opinion that a certain freedom from party ties should mark a member for a university, into whose election there may well enter some considerations different from those which are paramount in constituencies of the ordinary type. Arguments not without weight can be adduced in favour of the establishment of a second chamber on a vocational basis, but none of them are applicable to the House of Commons, where all members must be representative of their constituencies, and not of their profession, trade, or occupation. Nevertheless it is highly important that experience in different walks of life and in many vocations should, in fact, be represented there; and now that matters of public health and education, and important social questions in relation thereto, are so prominent in the public mind and in parliamentary discussion, it has become of great moment that medical knowledge and the medical point of view should receive adequate presentation and proportionate consideration. These they have not always received; nor, indeed, are they easy to secure.

It is well, therefore, that the medical members of the House of Commons are found among the three political parties in numbers not wholly out of proportion to the strength of those parties in general; but it is to be hoped that what in some quarters in the past has seemed to be a too narrow and rigid interpretation of what party loyalty involves may not interfere with the valuable service which the medical members, as individuals and as a group, may render to their profession as well as to the public whom they represent. It is well-nigh impossible that members elected on quite different grounds should reflect with absolute correctness the views of the profession as a whole or as an organized body, and it will certainly be found, in this as in previous Parliaments, that several of the medical members will express opinions about some matters relating to hospital management or the organization of health services which are entirely unrepresentative of those of their profession at large. The danger is that such expression may be taken as being more representative and authoritative than it is. In this connexion we would record our great regret at the defeat of Sir Richard Luce, whose work and services have been very valuable and much appreciated, and who was in a better position than any of his colleagues to gather the views of the organized profession. There will, however, be compensation for this if the medical members will all associate themselves with the Parliamentary Medical Committee, and if that committee be kept in close touch with the profession outside. Dr. Fremantle, Dr. Vernon Davies, and Dr. Drummond Shiels have been very helpful in this way, and such help may be expected to continue, though this may be affected by the appointment of Dr. Shiels to a post in the Government as Parliamentary Under Secretary for India. We offer our congratulations to him and to Dr. Christopher Addison, who returns to the House of Commons and to office as Parliamentary Secretary to the Ministry of Agriculture. Perhaps it may not be too much to hope now for help on the Parliamentary Medical Committee from Dr. W. E. Elliot, freed from the claims of office. A very welcome recruit should be found in Dr. Ethel Bentham, whom we congratulate as the first medical woman to enter Parliament. Mr. Somerville Hastings, too, resumes a seat which he formerly occupied; and among the newcomers are Dr. Joseph Hunter and Dr. Morris Jones. Professor Thomas Sinclair, by an unopposed return, continues to represent the Queen's University, Belfast, and so maintains, along with his lay colleague Sir Hilton Young, the personal connexion between the House of Commons and the General Medical Council. Of the unsuccessful candidates, we may specially regret, in addition to Sir Richard Luce, Dr. Haden Guest, who, however, is certain to reappear. Dr. R. A. Lyster and Dr. Stella Churchill would have represented an earnest section of the public health medical services, as would also, perhaps more widely, Dr. James Kerr.

It is understood that the Parliamentary Medical Committee is so constituted that M.P.'s for the universities, whether medical or lay, are members of it. This has proved to be a very wise and valuable arrangement. The personnel in this respect has been altered by the election of Miss Eleanor Rathbone as an independent representative of the combined English Universities. Her interest in social and family welfare, with which the medical profession is so intimately concerned, is well known. We would suggest that the committee might be appropriately strengthened by the inclusion of Sir Hilton Young, as a member of the General Medical Council.

In conclusion, we are confident that the medical profession, while feeling regret at the loss of the zeal and understanding of Mr. Neville Chamberlain, will sincerely welcome to their duties the new Minister of Health, Mr. Arthur Greenwood, and Miss Susan Lawrence, his Parliamentary Secretary. Mr. Greenwood is not without experience of the Ministry, having been Parliamentary Secretary in 1924, and will no doubt maintain the custom now established of conference with the profession on all occasions when they are concerned or likely to be of service.

PHYSIOLOGY IN RELATION TO PRACTICAL MEDICINE.

THE examination system, however necessary it may be, has long been recognized as an evil, not only by the victims, but by their teachers and by broad-minded educationists. Most students of medicine naturally concentrate their attention on the best way of satisfying the demands of the examiners, which militates against the acquisition of a sound knowledge of their subject of study. It has indeed been thought, and probably with good reason, that many of the ablest students are in one way or another the greatest sufferers from examinations. Furthermore, the curriculum is partitioned off into watertight compartments by periodical examinations, so that when the successful candidate gains his entrance to the pathological laboratories and the wards, he may fancy that biology, including therein anatomy and physiology, has become a thing of the past. With the lengthy and crowded state of the curriculum there is thus a real danger that in the final stages of his clinical work the student's memory, not only of the details, but of the principles of the underlying sciences, will have become dim and confused. The importance of correlating the subjects of medical education and of continuing instruction in the earlier sciences throughout the clinical years is now fully recognized, and in order to ensure that anatomy shall be applied, and that the student shall think physiologically and in terms of biochemistry, special courses have been recommended, and have been provided during the clinical years in the medical schools, though no doubt to a varying extent in different centres.

The era of morbid anatomy in the last century, when structural change was regarded as the cause and convincing proof of disease, has been superseded by the general attention paid to the diagnosis and methods of investigating disorders of function. Thus, the late Sir James Mackenzie laid down the principle that the vast majority of the symptoms of disease are disturbances of normal reflexes. The close relationship of physiology and its offspring biochemistry with pharmacology and therapeutics, pathology, and experimental medicine has ceased to be a new idea. The state of opinion is shown by the number and success of comparatively recent books dealing with the relations of physiology and practical medicine. Thus, to mention some works by British authors only, we have Dr. Robert Hutchison's *Applied Physiology* (1908), Dr. W. Langdon Brown's *Physiological Principles in Treatment* (1908, fifth edition 1924), Mr. A. Rendle Short's *The New Physiology in Surgical and General Practice* (1911, fifth edition 1922), Dr. Sampson Wright's *Applied Physiology* (1926, second edition 1928), Professor R. J. McDowall's *Clinical Physiology in Relation to Modern Diagnosis and Treatment* (1927), and the most recent of all, *Elementary Medicine in Terms of Physiology* (1929), by Dr. D. W. Carmalt-Jones, consulting physician to the Westminster Hospital and professor of systematic medicine in the University of Otago, New Zealand.

The best way of correlating physiological principles with the manifestations of disordered function is open to discussion, and possibly the most successful solution may be provided by the concurrent employment of different methods, such as separate courses of applied physiology by the physiological lecturers, and constant emphasis on the relation of physiology to symptoms in the course of their ward rounds by the clinicians, who must therefore have an up-to-date knowledge of the subject. In view of the greatly increased amount to be learnt by the present-day student it has been suggested—from a strictly utilitarian point of view, and perhaps with insufficient imagination of what developments in the future may bring within the range of practical medicine—that anatomical and physiological teaching should be regulated by the existing needs of the clinicians. To quote a somewhat extreme position, it appears to have been proposed in the United States of America that the clinician should examine the students in their knowledge of the pre-clinical subjects. This suggestion was slyly countered by Professor C. J. Wiggers[1] of the Western Reserve University, Cleveland, Ohio, with the alarming comment that, for the benefit alike of the students and the clinicians concerned, such clinical examiners should periodically be required to furnish evidence, by examination or otherwise, that they are masters of the subject they attempt to adjudicate upon. But a good deal can and has been done by introducing into biological work types of protozoa and animals met with in the study of disease, and by illustrating normal physiology—for example, of the nervous system—by patients showing the results of inhibition or abolition of the normal conditions. Further, the use of laboratory methods in demonstrating normal function can be extended to, and illustrated by, abnormal and artificially induced conditions of function which in turn can be correlated with conditions of disease in the human subject.

It is, of course, impossible to exaggerate the importance of applied physiology in the art of medicine; the two influence and benefit each other. In the past, more than in the present, medicine helped physiology; but the debt of medicine to the experimental method is ever increasing, so much so, indeed, as to narrow or even to obliterate any line of division between applied physiology or experimental medicine and the science and art of medicine. The closer the correlation between the two, and the more intimately the physiologists and the physicians work together and pool their knowledge, the more will medicine approach an exact science.

PREVENTION OF FIRE IN X-RAY DEPARTMENTS.

SOME obscurity still exists as to the nature of the heavy brown fumes which were liberated as the result of the explosion that occurred at the Cleveland Hospital, Ohio, on May 15th. That they were fumes of bromine with hydrocyanic acid was suggested by the coroner's statement (recorded in our issue of May 25th at page 963) to the effect that poisoning by these gases had been proved to be the cause of death in a number of the victims. It is probable, however, that the fumes consisted in large part of carbon monoxide and nitrogen peroxide, combustion products of nitrocellulose, the material used in the manufacture of the inflammable type of film. Not only is the amount of silver bromide in films relatively small, but it is improbable that bromine would have been liberated in the toxic quantities reported from so stable a compound. While, however, it may be argued that only an academic interest attaches to the composition of the liberated gases, there is no doubt that, so long as the inflammable type of film is used, protection against the hazards of fire is of immediate practical importance. In a letter published in our issue of June 8th (p. 1057) the X-Ray and Radium Protection Committee now investigating the latter problem in this country made the following provisional recommendations: (1) care should be taken to ensure that x-ray films are handled in such a manner as to reduce to a minimum the danger of fire; (2) films should be stored in filing

[1] Wiggers, C. J.: *Journ. Amer. Med. Assoc.*, Chicago, lxxii, xxi, 1.

cabinets or cupboards, leaving as few as possible lying open for reference; (3) on no account should smoking or naked lights be permitted near any film store; (4) in institutions where considerable numbers of films may be accumulated arrangements should be made for a special store, preferably isolated. With these recommendations it is interesting to compare those made by Mr. R. D. Hobbs of the Western Actuarial Bureau, Chicago, who, in an article in the November, 1928, issue of *The Modern Hospital*,[1] reported a fire which broke out in a room used for storing films and x-ray equipment in the Memorial Hospital, Albany, New York. Unexposed films, Mr. Hobbs suggests, should be stored in containers constructed of lead, or lead-lined, on shelves two feet above the floor, or in double wall cabinets, vented to the outside air. The amount of unexposed films in standard containers kept outside the fireproof vaults should not exceed 50 lb., and all films should be transferred to storage as quickly as conditions permit. In discussing the use of the so-called non-inflammable films—which, in fact, are inflammable, though they burn slowly and without the production of poisonous gases—he points out that their disadvantages are increased cost and a tendency to roll and curl, and draws the conclusion that property and lives may be endangered to facilitate handling and filing. The floor and walls of storage vaults should, he suggests, be of brick at least 8 in. thick, or of reinforced concrete at least 6 in. thick; and double fireproof doors should be provided, one at each face of the wall. The inner door should be made to close automatically; the outer, self-closing, should be of a swinging type, and made to close into a jamb so as to prevent the passage of flame around the edges. A vent to the open air should be provided, giving a clear opening of at least half a square inch per cubic foot of room. Mr. Hobbs recommends a number of general precautions, the adoption of which would demand nothing but a little intelligent organization. At no time, he suggests, should waste negatives and film scraps be allowed to accumulate on tables or floors; they should immediately be placed in fireproof metal cans fitted with self-closing spring-hinged covers. Only standard electrical fixtures should be permitted in rooms where films are filed or handled; the use of portable lights on extension cords should be forbidden. In each room there should be a fire extinguisher, and the doors should be arranged so as to make egress easy. Film negatives should be filed as soon as possible in heavy manila envelopes, and should be arranged so that from time to time useless negatives may be weeded out. The diffusion glass of film illuminators should be cool to the touch, and there should be no unnecessary display of film negatives in lighted illuminators. Smoking should be forbidden in rooms where films are stored, and no films should be placed within two feet of steam pipes, radiators, or other sources of heat.

LA SIGNORA DALLA LAMPADA.

THE present vogue of unsentimentality, expressed in a growing tendency to represent ideas and personalities generally regarded as beautiful and inspiring as being humdrum, if not actually paltry, has led in America to the coining of a new verb—to debunk. To debunk is to remove the whitewash from historical characters, or, conversely, to prove that they are only as black as they have been painted. No illusions may hope to elude the vigilance of the modern debunker, except his own and those of his own age and place. His happy hunting ground is the nineteenth century, to whose complacency and self-righteousness he feels a superiority which, it is common knowledge, is neither complacent nor self-righteous. In America he has debunked George Washington; in England, the eminent Victorians. Mr. Lytton Strachey has applied the process to Florence Nightingale, damning her with supercilious praise and throwing into relief those of her characteristics which became less amiable as she grew older. The author of the play *The Lady with the Lamp*, probably influenced by Mr. Strachey, has also emphasized the harder, more masculine side of Florence Nightingale's character at the expense of its more lovable, more feminine aspects. The account by Dr. E. W. Goodall[1] of an interview with Florence Nightingale when she was 73 years old presents her in so different a light that one may suspect these authors of having been influenced too much by the fact that their subject belonged to the Victorian instead of to their own more enlightened age, of having avoided one extreme of bunk only to be guilty of another. We are pleased to turn from their writings to a most graceful tribute paid to her memory and to the British medical profession by Colonel Arturo Casarini, M.D. (one of the delegates to the recent congress in London), in a pamphlet dedicated by the *Italian Journal of Military Medicine* to our Royal Army Medical Corps. Dr. Casarini, in "La Signora dalla Lampada (Fiorenza Nightingale)," opens with a short but vivid sketch of the influence of Rome on Britain, giving some account of Roman remains in this country, and reproducing appropriately a photograph of the monumental stone now in the Newcastle Museum, erected on Hadrian's wall to a young army surgeon of the Tungrian Cohort. That the influence has not always operated in one direction only is suggested by Colonel Casarini's handsome tribute to our nation for its sympathy and help in the stormy days of the last century when Italy fought to overcome the oppression of her alien masters. Florence Nightingale, who reformed the methods of nursing the sick throughout the world, though bred in England, was born in Italy and named after her birthplace, Florence. For many years she prepared herself by all available means for what was to prove her great mission; she studied the theory and practised the art of nursing wherever and whenever she could, and she visited and studied the organization of hospitals and infirmaries both at home and abroad. In the Institute of Protestant Deaconesses at Kaiserswerth she remained for six months learning the principles and details of hospital management; in Paris she studied the organization of the hospitals under the charge of the Sisters of St. Vincent de Paul. When at last, in 1854, she was invited by Sidney Herbert, Secretary of State for War, to proceed to Scutari to reorganize the barrack hospital, there was no one more fitted to undertake the task than she. Colonel Casarini reminds us that the appeal on behalf of the sick and wounded at Scutari was made by Sir William Russell, the *Times* correspondent, who described the superiority of the French medical services and the value to the French army of the Nursing Sisters of St. Vincent de Paul. In response to his indignant demand that the women of England should go out and nurse their countrymen, Florence Nightingale wrote offering her services, in a letter which crossed one from Sidney Herbert inviting her to go at once to the Crimea. Appointed with full powers, she set out for Turkey on October 23rd, 1854, with thirty-eight nurses, including ten Sisters of St. Vincent de Paul. She reached Scutari on November 4th, in time to attend to the wounded of Balaklava and Inkerman. The story of her work at Scutari and elsewhere is one of the most inspiring in English history, and we thank Colonel Casarini for telling it so beautifully. He concludes his work with a tribute to the Italian and British soldiers who fought and fell side by side in the great war, and to Miss Hilda Wynne, who, on many fronts, including Piave and Pralungo, proved herself a worthy follower of Florence Nightingale.

THE STUDY OF TISSUE CULTURES.

THE work at present carried out at the Strangeways Research Laboratory, Cambridge, had its origin in a theory developed many years ago by the late T. S. P. Strangeways, Huddersfield Lecturer in Special Pathology, University of Cambridge, that our knowledge of a disease could best be advanced by a study of its pathology in the living body. We are reminded in a recently issued report[1] on the work of the laboratory that Strangeways's first studies of the cytology of the living cell were in connexion with the problems of rheumatoid arthritis, it being for the investigation of the pathological processes involved in this condition that he elaborated his technique for the cultivation of cells *in vitro*. He soon realized, however, that this method of approach was likely to help in the elucidation of wider problems connected with normal and abnormal tissue growth, and, gradually emptying his hospital wards of arthritic patients, he gave himself over almost entirely to investigating the technique and applications of tissue culture. Since 1920, states the report, the work done in the laboratory has related to four main subjects—cytology, embryology, radiology, and cancer. Strangeways's own research, which produced many valuable and interesting observations on the division, structure, and behaviour of living cells, has been continued by his daughter, who has recently studied one of the cytological problems of wound healing—namely, the question as to whether the cells of newly formed connective tissue may be derived from wandering cells of the blood. Of interest in connexion with the origin of various types of cerebral tumours is an investigation by Drs. Wells and E. A. Carmichael, who are studying the cytological development of the central nervous system by cultivating embryonic brain *in vitro*. The technique of embryological investigation, initiated by Strangeways's discovery that tissues cultivated in a suitable medium continue to undergo progressive structural differentiation, has been elaborated and successfully applied to a study of the development of the isolated limb and eye rudiments of early fowl embryos. The results of these and other embryological studies have demonstrated that complex tissues are able to develop from completely isolated rudiments without the control of nerves or blood vessels. Dr. J. G. H. Frew, in studying the embryology of the blow-fly, devised a method for growing fragments of its larvae *in vitro*, obtaining thereby important information about certain physiological factors involved in the metamorphosis of the maggot into the adult fly. In 1920 Strangeways began to study the effect of irradiation on the tissue cultures—an investigation which is making it possible to discriminate between those effects which are due to the action of the rays upon the cells and those due to the reactions of the body as a whole. It is further rendering possible the precise analysis of the effects of rays upon cell division—a subject of increasing importance to medical science. Since Strangeways's death Dr. Spear and Dr. Canti have investigated the effects of radium on cell multiplication, their results having an important bearing on the treatment of cancer by radiological methods. Dr. Spear, in his studies on the effect on cell division of temporary exposure to low temperature, has obtained results which resemble those obtained by irradiation with radium. Work on tumour growth was begun in 1925, when a study of Jensen's rat sarcoma was made by Dr. Fell and Dr. Andrews. In continuation of this study Dr. Andrews has conducted a series of researches on the relationship of acidity and cell degeneration to tumour growths, and has carried out a great number of experiments on the physiological conditions stimulating the multiplication of normal and cancer cells. As many of our readers are aware, Dr. Canti, using tissue cultures prepared in the laboratory, has evolved a technique for making cinematograph films of growing tissues, and has photographed cells actually under the influence of radium. Unfortunately, many lines of research have to be neglected owing to lack of funds, and if the work now being carried on at the laboratory is to continue its income must be increased sufficiently to enable it to provide salaries for a small permanent staff. As reported in our news column, a course of instruction in the technique of tissue culture will be given at the laboratory from July 9th to August 10th. Only a limited number of applicants can be received, and those wishing to take the course should apply, not later than June 30th, to Dr. H. B. Fell, Strangeways Laboratory, Cambridge.

COTTON CLOTH FACTORIES REGULATIONS, 1929.

THE Cotton Cloth Factories Regulations, made by the Secretary of State under a new short Act known as the Factory and Workshop (Cotton Cloth Factories) Act, 1929, came into operation on May 15th, the regulations under the Act of 1911 being, of course, repealed. These new regulations materially alter the requirements hitherto governing the conduct of cotton cloth weaving sheds, and give effect to certain recommendations of a departmental committee, to which weavers and manufacturers had agreed to submit their opposite contentions respecting the effects of humidification and the necessity for its abolition. The committee had agreed with the employers that humidification, as practised under the old regulations, did not adversely affect the sickness rate of workers in "humid" sheds as compared with that of workers in "dry" sheds, but held that the weavers were right in contending that the practice has a tendency to produce fatigue and limitation of output, and could, without detriment to the process, be subjected to further restriction. Both sides are doubtless pleased to have scored to this extent, though the real gain apparently lies in the clearing away of obstructions to an agreed set of regulations. On comparing the regulations with the recommendations one is immediately struck with the failure to do away completely with the old subdivision of weaving sheds into "humid" and "dry." Good reasons were given for suggesting this change, and, the recommendation to empower the Chief Inspector of Factories to grant exemptions in approved cases having been adopted, it is surprising that the complete cut was not made. Most of the requirements apply to "any weaving shed," but the two classes are still recognized by including them in the definitions and using the distinctive terms in three of the regulations. It is also to be regretted that the Secretary of State has not adopted the sound and practical suggestion that plans of new sheds and of alteration to buildings should be submitted to the factory department for approval. The new Order does, however, carry out most of the recommendations, and should materially reduce the discomfort to the weaver without adversely affecting production. Artificial humidification must cease when the wet bulb temperature reaches 72.5° F., instead of at 75° as formerly, or when the scheduled relationship between the wet and dry bulb readings is exceeded; if average readings exceed 85° wet bulb, work must cease until this limit is regained; the minimum temperature permitted is 50° dry bulb for the first half-hour of the day, and 55° subsequently. The taking of readings does not now require a representative from both employers and weavers, and the records are to be sent to the inspector monthly instead of immediately. Top lights are to face between north-east and north-west; if the average of the readings of the hygrometers reaches 72.5° wet bulb, ventilation is to be continued during dinner hour, or for two hours after work ceases, as the case may be; cloak rooms are compulsory for humid sheds built after February 2nd, 1888, and for "dry" sheds built after January 1st, 1928; defects in the working of appliances

must be reported, and only individuals duly authorized may interfere with them or with hygrometers. It is pleasing to note that the carbon dioxide standard, though now said to be unscientific, is still regarded as of practical utility and is not to be scrapped; inasmuch as it has been the big lever in producing workable schemes for combining ventilation and humidification, it should still be effective in keeping these up to the mark. Regulations concerning steam-pipes, boilers and flues, whitewashing, and hygrometers have not been altered.

BLOOD-VESSEL TUMOURS OF THE BRAIN.

ALTHOUGH vascular tumours of the brain are rare, their importance has aroused considerable interest, and Cushing and Bailey's useful monograph on the subject was reviewed at some length in our issue of May 25th (p. 958). In this connexion it may be mentioned that Mr. R. Foster Moore records a case of haemangioma of the meninges involving the visual cortex in the May issue of the *British Journal of Ophthalmology*. Mr. Foster Moore's patient was a boy, aged 12, who complained of defective vision of the left eye; there was a naevus of the left half of the face involving the eyelids. Examination of the fields of vision showed, however, that right homonymous hemianopia was present. He suggested that a naevus of the visual cortex was the likeliest cause of the condition, and that a skiagram should be taken with this in view. A large wedge-shaped tumour was revealed; it consisted of a new growth of large vessels, and was obviously a meningeal haemangioma: its base lay at the occipital pole immediately above the tentorium, and was, therefore, closely related to the visual cortex. Mr. Foster Moore draws attention to various other cases of the same kind that have been noted since 1922, when, in the *Journal of Neurology and Psychopathology*, Parkes Weber reported on a tumour recognized by *x*-ray examination of the living patient to be a calcified haemangioma. He mentions the frequent association of these tumours with such ocular abnormalities as buphthalmos and heterochromia iridis. In view of the frequency with which this first abnormality is found in cases of intracranial haemangioma, he advises that a skiagram of the skull should be obtained in all cases of buphthalmos, and also that a watch should be kept for the possible association of choroidal melanomata with intracranial tumours.

THE CARE OF EPILEPTICS.

IN the *Journal* of June 1st last (p. 1003) we gave an account of the provision for the care of epileptics made in several countries of Europe and the United States of America, and drew attention to the fact that there is an insufficiency of suitable provision in this country. The Permanent Committee on Epileptics, in response to whose inquiries much of this information was collected, has now issued to the officers of all county councils and county borough councils an appeal to consider the claims of epileptics when preparing administrative schemes under the Local Government Act, 1929. It is pointed out that there are numbers of epileptics in the general Poor Law institutions, and that this is not a satisfactory arrangement. Some of these epileptics are insane; a larger number are mentally defective; but a considerable proportion may be classed as mentally normal. These last often feel their position keenly, and really require separate institutional accommodation. The committee hopes, therefore, that, in addition to the use of their powers under the Mental Deficiency Acts and the Education Acts, councils will make such provision their special and early care. This circular letter to the county and county borough councils is an example of vigilant and appropriate action which may be commended to the notice of Divisions and Branches of the British Medical Association, and to others who are anxious for the best use of the opportunities afforded by the public health provisions of the new Act.

WE regret to announce the death of Sir William J. Thompson, M.D., Past-President of the Royal College of Physicians of Ireland, and for many years Registrar-General for Ireland.

THE L.C.C. AND TRANSFERRED HEALTH FUNCTIONS.

THREE PRINCIPAL MEDICAL OFFICERS.

THE London County Council, at its meeting on June 11th, decided, as from October next, to increase the fixed staff of its Public Health Department by three principal medical officers. This increase is the first result of the arrangements which have to be made consequent upon the transfer to the Council of Poor Law work under the Local Government Act, 1929. While such transfer does not take place until April next, it is felt that in view of the magnitude of the new duties to be undertaken and the necessity for ensuring that complete arrangements shall be made for the efficient organization and administration of the transferred functions as from the appointed day, adequate staffing arrangements should be made during the preliminary period. The officers in question, therefore, will be appointed before the Council rises at the end of July for the summer recess. The salary of each of the three officers will be an inclusive one of £2,000 a year, rising by annual increments of £100 to £2,500 a year. It should prove attractive to men with the highest qualifications for responsible work of this kind. Particulars of the new posts appear in our advertisement columns.

The Establishment Committee, in a report to the Council, estimates that the total staff of the 81 hospitals and infirmaries to be transferred to the Council from the Poor Law guardians and the Metropolitan Asylums Board numbers 16,000 persons, of whom no fewer than 400 are whole-time medical officers, and at least 7,500 are members of the nursing services. These figures do not take account of the expert technical staff engaged in consultative medical and surgical work and laboratory investigation, of which the total number engaged, whole-time and part-time, is upwards of 150. It is not possible at present to make any detailed statement as to the staff which will be required to assist the Council's medical officer of health (Dr. F. N. Kay Menzies) in carrying out the increased volume of work to be dealt with in his department, but it is considered necessary as a first step to appoint three principal medical officers of higher rank and salary than that of the present senior medical officers of the service. It will then be possible to reorganize the department on the basis of three divisions, thereby placing each of these principal officers in a highly responsible position, and providing for the necessary co-ordination of the existing and transferred health functions.

THE KING.

SINCE the publication of the note in our last issue (p. 1050), the following bulletin has been issued from Windsor Castle, dated June 10th: "His Majesty the King is making progress. The abscess is diminishing in size. The general health is good." During the week His Majesty has been well enough to receive outgoing Ministers and attend personally to business incidental to the appointment of the new Cabinet; he has also spent some hours out of doors in the grounds of the Castle. Our readers will have concluded from the earlier bulletin that a collection of pus had formed under the site of the old scar. This is now draining, and the abscess has nearly healed. *X*-ray examination shows the presence of one or two minute sequestra. There is a good prospect of the condition clearing up without further intervention.

CHEMICAL FACTORS IN THE CONTROL OF THE CIRCULATION.

CROONIAN LECTURES BY DR. H. H. DALE.

At the Royal College of Physicians on June 4th, 6th, and 11th, Dr. H. H. DALE, F.R.S., delivered the Croonian Lectures, his general subject being "Some chemical factors in the control of the circulation."

VASOMOTOR HORMONES.

In his first lecture he recalled that six years ago in the same assembly he delivered the Oliver-Sharpey Lectures, when his subject was the activity of the capillary blood vessels. His aim then was to bring together the evidence, much of it of recent date, on the independent contractile activity of those minute vessels and its bearing on certain problems of physiology and pathology. Some of the investigations were concerned with the vascular effects of certain intensely active principles, one of which, adrenaline, had long been known as a natural hormone. Two other bases, rivalling adrenaline in the intensity and evanescence of their activity on the tone of the small blood vessels, were also mentioned—namely, histamine and acetyl-choline—but there was then no evidence which seemed to justify the supposition that either of these substances was a natural constituent of the animal body.

During the last six years evidence from a number of sources had brought about a great change in the situation. Sir Thomas Lewis had published a systematic review of certain researches, the central interest of which from this point of view was the recurring evidence of liberation from injured or irritated cells of a chemical substance closely resembling histamine in its action and responsible for the vaso-dilatation and wheal formation in the immediate neighbourhood of the lesion. Meanwhile, the lecturer's own associates had been making progress, far beyond expectation, in the isolation, in pure form from extracts of animal tissues, of substances producing actions on peripheral blood vessels. From an entirely different direction evidence had appeared indicating that those changes in the automatic rhythm of the heart which were produced by stimulation of the vagus on the one hand, and of the sympathetic nerve supply on the other, were not the results of the direct passage of nerve impulses to the heart muscle, but were mediated by the liberation of chemical principles having inhibitory or excitatory actions.

Therefore it had seemed useful to attempt a review of the evidence concerning some of these chemical factors in the control of the circulation, passing under consideration, in the first place, the previously known substances which had claims to be regarded as circulatory hormones in the true sense—namely, adrenaline and the vaso-constrictor principle of the pituitary body. It was desirable to restrict the word "hormone" to its original meaning—namely, an active principle formed in one organ and carried by the blood to others in which it produced its specific pulsating or pharmacodynamic effect. In this sense adrenaline might be taken as a perfect type of the hormones, and the pituitary vaso-constrictor principle, which might be referred to as "vasopressin," had at least a presumptive claim to be included in the list.

Adrenaline.

The knowledge regarding adrenaline was more complete than in the case of any other hormone. It was a relatively simple derivative of catechol, and was successfully produced by synthesis many years ago. Its action, when applied through the circulation, was a very evanescent one, unless it was injected in quantities altogether beyond the physiological range. Accordingly it was admirably fitted for the temporary reinforcement, in response to sudden emergency, of the effects of true sympathetic nerves on almost all organs supplied by them. The output of adrenaline from the suprarenal medulla was under nervous control, responding to impulses in the splanchnic nerve fibres running to the gland. The consequent gush of adrenaline into the venous blood accompanying a sudden emotion, and the adaptation of its effects, especially on the circulation, to the physiological needs of the emergency, had already been emphasized. It must be supposed that adrenaline was carried in almost equal concentration to all parts of the circulatory mechanism, reproducing the sympathetic effects on the heart-beat, and affecting the blood vessels in the sense of their response to sympathetic impulses. The variations of this response in intensity and even in direction produced large variations in the relations between the vascular tone in different systems. The vessels of the gastro-intestinal canal were apparently in all animals more sensitive to the vaso-constrictor effect than those of the skeletal muscles, so that a dose of adrenaline entering the general circulation would tend to produce a redistribution of the blood supply in favour of the muscles and at the expense of the alimentary canal. Discussing the effect as seen typically in the cat and dog, he suggested that the acceleration of the output of adrenaline from the suprarenal medulla might be regarded as an item in a general series of changes replacing the physiological conditions favourable to contemplative digestion by those which fitted the animal for combat or flight.

Vasopressin.

The pituitary vasomotor principle presented in many respects a contrast to adrenaline. Opinion had been sharply divided as to whether one or several active principles were responsible for the effects produced by extracts of the pituitary posterior lobe. During the past year the matter had been settled by Kamm and a team of workers, who had obtained a powerful vaso-constrictor fraction, which they termed "vasopressin," which had but slight action on the uterus: Another fraction which they termed "oxytocin" was powerfully stimulating for the uterine muscles but almost inactive on the blood vessels. The actions of the whole extract on the plain muscle of the uterus and on the vascular tone were, therefore, certainly due to different principles.

Of the chemistry of vasopressin little was known. It was not a simple base, like adrenaline or histamine. Injected into the circulation, it was not, like adrenaline, rapidly destroyed. Its action was long and persistent. For its true hormone function and the manner in which it came into action, the evidence was remarkably incomplete and indirect. It was difficult to believe that a substance so potently active on artificial injection should be concentrated in a structure without other known function, with no provision for its carriage by the blood to the tissue in which its intense activity became effective.

So far as its action had yet been analysed, vasopressin appeared to produce its effects on the circulation by increasing the tone of the minute vessels without any discrimination corresponding to their nerve supply. The strongest evidence in favour of the function of vasopressin as a true hormone was its occurrence in such quantity in a tissue in which no local function could be imagined for it. It might be that the function of the pituitary hormone was to provide yet another safeguard against circulatory collapse by a general and undiscriminating maintenance of tone in the small blood vessels when sympathetic impulses and adrenaline alike began to fail under the stress of prolonged and excessive demand.

Control of Vascular Tone.

Looking at the function of the nerve centres controlling vascular tone, it was almost a commonplace to say that, like that of many hormones which had a general distribution through the blood, the control was predominantly tonic and vaso-constrictor. This control, whether by the nerve centres or the true hormones, might be regarded as adapted to the maintenance of the average vascular tone needed for an efficient circulation, to its adjustment in relation to the pressure created in the large arteries by the heart's activity, and to mass variations in the distribution of the blood supply as between one system and another or as between one organ and the rest of the body.

A large proportion of the vascular reactions of the body, however, were of quite different type, and fitted to effect

a much finer adjustment of the blood supply to more closely localized requirements. Into this class came all the reactions most accessible to observation in the skin and superficial mucous membrane, but they occurred in almost all organs in which a localized stimulus, irritation, or injury caused a local vaso-dilator reaction. According to Lewis, the immediate stimulus to these local vascular reactions was a chemical one. Some substance was liberated from the injured cells which directly dilated the minute vessels and rendered their walls abnormally permeable. Lewis had no direct evidence as to the nature of this chemical agent, but among known pure substances he found one—the base histamine—which reproduced the complex with detailed fidelity when introduced in minute dosage into the epidermis. The lecturer regarded it as highly probable that the substance recognized by Lewis was either histamine itself or some loose combination owing its action to histamine.

Local Vaso-dilator Reactions.

In his second lecture Dr. Dale devoted himself to the physiological significance of histamine, which, he said, was first made synthetically, as a chemical curiosity, by Windaus and Vogt. The first hint of its physiological interest was obtained when Barger and the lecturer were seeking for the principle in certain ergot extracts, which they had recognized by its potent stimulating property on the muscle of the isolated uterus, associated apparently with a pronounced depressor action, when administered intravenously to a cat. This substance was identified from ergot as the base now known as histamine. When Laidlaw and he came to investigate its action in detail, the remarkable resemblance between its effects in different species and those which, in the same species, had then recently been described as characteristic anaphylactic shock, soon became clear. It became clear also that in each species the corresponding physiological complex was produced by various organic extracts and products of protein digestion, in which the presence of unknown "depressor principles" had long been recognized.

The first definite claim to the chemical identification of histamine as the essential depressor constituent of a number of animal organs and tissues was made by Abel and Kubota in 1919. Their evidence, unfortunately, failed to carry complete conviction. They isolated histamine salts from two of the many tissues investigated, but their findings in both cases were open to criticism. Their conclusions, as more recent work had shown, were substantially correct, but the evidence left those conclusions open to doubt, and they met with no general acceptance.

Histamine as a Normal Constituent of Tissues.

About 1926 interest arose in claims made for injection of extracts prepared from the liver as a specific treatment of morbidly high blood pressure. The particular problem here was to discover the chemical nature of the substance producing the immediate depressor action, which was being used in the laboratory as an index of the value of the extract. Two different factors were easily recognized in the vaso-dilator activity of this extract: one of them an action resembling that of choline, affecting the stronger arterioles, and the other an action resembling that of histamine, confined to the minute vessels and capillaries, but exhibiting chemical properties quite unlike those of histamine itself. At several stages he and other workers had almost concluded that it could not be histamine, and were only saved from this error by observing that when histamine was added to the extract its chemical behaviour showed similar anomalies. Eventually both choline and histamine were isolated, being obtained not merely in sufficient quantities for complete chemical identification, but in such amounts as to make it unnecessary to suppose that any other more complex or unidentified principles contributed to the depressor vaso-dilator action. Attention was next turned to the lung, which yielded an extract having a peculiarly intense depressor action. Here almost all the activity was found to be of a histamine type, and there was comparatively little difficulty in isolating the histamine.

Dr. Dale then showed a table giving the figures obtained in a survey of a number of organs, the extracts being assayed for histamine by the physiological method. He drew attention to the relatively enormous histamine content of the lung and the low position of the skeletal muscle in the scale. It had been possible to test whether histamine thus extracted from a tissue such as the lung was present during life or formed rapidly after the death of the cells. The experiments showed that histamine had evidently as good a claim to be regarded as a normal constitutent of the living cell as any other substance which similarly conservative methods could extract. It must either be existing during life or be formed in the very act of cellular death.

Lewis's H- Substance.

All this work had an important bearing on the conclusions which Lewis and his colleagues were reaching independently. Lewis had evidence that the living cells of the skin, when subjected to irritation or injury, liberated a substance with an action remarkably like that of histamine. The suggestion was that this substance—Lewis's H- substance—was histamine itself, not newly formed in response to the stimulus, but already existing in the cell interior and only becoming active on liberation. Chemically identifiable histamine had not yet been obtained from the skin, but Harris, in Lewis's laboratory, had no difficulty in proving that the skin of man and other mammals, extracted by processes similar to those used for other tissues, yielded a substance physiologically indistinguishable from histamine.

So far all seemed to be in favour of the identification of the substance released from living cells in response to injury as histamine. Lewis, however, while acknowledging the many points in favour of such identification, preferred to refer to the substance liberated during life as the H-substance—a name designed to leave the question of identity open. A complete proof of the identity could only be obtained if the H- substance could be trapped in oedema fluid or in blood or lymph. The H- substance, by common consent, was normally present inside the cells of the tissue. When attempts were made to extract it, histamine was invariably obtained. If H- substance was not histamine, therefore, it was a substance immediately yielding histamine.

Difficulties of Identification.

Dr. Dale proceeded to discuss some of the difficulties in the identification of the H- substance with histamine. His general conclusion was that while some of the phenomena connected with the H- substance were not easy to reconcile immediately with the supposition that it was free histamine, there were others which would be equally difficult to explain if it were supposed to be a much more complex and indiffusible body. If these difficulties only were in question it would seem rational and entirely compatible with what was known of its properties to suppose that histamine was the active constituent of the H- substance, and that the latter, according to the varying conditions of its liberation, might represent all grades of molecular association, from free histamine to relatively large complexes. The term H-substance would then no longer represent a hypothetical chemical entity, which might be histamine or something entirely different; it would represent a group of loose molecular combinations, of varying complexity, in which histamine might be liberated from cells during life, and to all of which it might impart its characteristic physiological actions. More serious difficulties arose, however, if the attempt was made to apply such a conception to all vertebrate animals. In the case of the frog, for example, the lack of vaso-dilator action by histamine, which Laidlaw and the lecturer had indicated, constituted a genuine and complete discrepancy.

Viewed as a whole, the evidence seemed to indicate that histamine, in the mammals chiefly investigated, was a generally distributed constituent of the cells of the animal body, inert while it remained within the cell, but intensely active in producing local vaso-dilator reactions when appropriate stimuli released it from the cell into the tissue fluid, either free or in molecular combinations of varying complexity. In certain vertebrate types, such as the frog, some other basic substance, possibly allied to it, appeared to replace histamine in distribution and function.

Physiological Significance of Histamine in the Lung.

In discussing some of the physiological questions which arose out of this, the lecturer referred especially to the presence of histamine in so large a quantity in the lung. The fact that in the lungs alone there might be as much of this intensely active substance as there was of adrenaline in the suprarenal gland of the same animal, and that this organ, with its small intrinsic metabolism, had no obvious need for local variation of the diameter of its small vessels, naturally raised the question of an internal secretion of histamine from the lung, and the consequent function of histamine as a true hormone. There was no evidence of such a process, and it could only be recognized as a mere possibility. The alternative possibility, quite unsupported by any direct or adequate evidence, was that histamine, thus accumulated in the lung, might represent material which, having served its function elsewhere in more active tissues and escaped into the venous blood, had been caught on its way through the lung vessels and held there pending destruction by some method. The physiological significance of histamine in the lung was a problem deserving further investigation.

Looking at all the evidence for the normal physiological functions of histamine in various organs, the lecturer thought it might be concluded that histamine was practically limited to actions in the immediate neighbourhood of its liberation. On several occasions he had suggested that the liberation from the active cell of a substance acting like histamine on the minute vessels in its immediate neighbourhood should provide a perfect mechanism for the fine adjustment of the blood flow to the fluctuating needs of small tissue units; but there was still no more than this teleological argument in favour of such a process.

VASO-DILATOR SUBSTANCES: FURTHER CONSIDERATIONS.

In his third and concluding lecture Dr. Dale addressed himself further to the consideration of histamine, and entered upon a long and detailed argument concerning its significance in connexion with anaphylactic and allergic reactions.

Anaphylaxis and Histamine Action.

At the time when the activity of histamine was discovered, the rediscovery of experimental anaphylaxis in the guinea-pig, and the dramatically fatal character of the shock in that species, aroused fresh interest in the physiological details of the reaction as seen in different animal types. It seemed natural to suppose that the anaphylactic shock following the injection of Witte's peptone into the dog or guinea-pig was due to the liberation of a protein cleavage-product in the circulation by digestion of the reinjected antigen, and when the action of so simple a substance as histamine was found to produce the principal features of the shock, with their characteristic contrasts in the different species, it was again natural that it should be identified with this hypothetical circulating anaphylatoxin. This theory, however, had never appealed to the lecturer, and later his own investigations, together with those of a number of observers, convinced him of the correctness of the view which attributed the symptoms of the anaphylactic reaction, not to the formation of a poison in the blood, but to the reaction between the antigen and a precipitating antibody located in the cell protoplasm. The knowledge now available seemed to make the matter clear. Lewis, finding that a local anaphylactic reaction in the human skin presented the familiar "triple response" of the blood vessels to a local injury, concluded that the union of antigen and antibody in the sensitized cells acted, like any other injurious stimulus, by releasing his pre-formed H-substance. Such a conception appeared to the lecturer to fit all the known facts, and to make clear the meaning of many which were difficult to interpret on any other theory. It was difficult, with the earlier conceptions, to explain why, in each species, only those cells apparently should become sensitive to the foreign antigen, and react to its reinjection, which had normally a special sensitiveness to histamine. There was now no necessity for assuming such preferential sensitization of the cells which participated in the overt reaction. Cells of other types might be assumed to contain the specific antibody and, as the result of its union in their protoplasm with the foreign antigen, to liberate pre-formed histamine; but only those cells which, in each species, were sensitive to histamine would exhibit the physiological reaction thereto. The effect thus produced could arise in one of two ways: either the histamine might be liberated from the reacting cells, or anaphylactic injury of the cells of some large organ, such as the liver, might liberate histamine into the general circulation in such quantity as to produce its effects in the body generally, and thereby cause a histamine response in cells not themselves sensitized to the antigen. Dr. Dale proceeded to trace these alternative processes as the central features in the shock as seen in the guinea-pig in the one case and in the dog in the other.

Acetyl-choline.

After some further remarks on allergic reactions and anaphylactoid phenomena, Dr. Dale turned to the action of an entirely different type of vaso-dilator substance which resembled histamine in certain features of its scientific history. Like histamine, the simple quaternary ammonium base known as choline was made in the chemical laboratory long before it acquired a physiological interest. His own interest in it was first aroused, again as in the case of histamine, by the discovery of its presence in certain extracts of ergot. On making a more systematic investigation of its actions on various organs he was struck by the remarkable parallelism between its effects and those produced by stimulation of parasympathetic nerves. It showed an extraordinary instability when injected into the blood stream, presumably being hydrolysed with the liberation of the relatively inactive choline. Accordingly, its parasympathetic effects were even more rapidly evanescent, as well as more powerful, than the sympathetic effects of adrenaline produced under like conditions. During more recent years he had observed that, apart from its parasympathetic and vaso-dilator effects in minute doses, readily annulled by atropine, acetyl-choline exhibited, when injected in larger doses after atropine, a powerful nicotine-like action on ganglion cells, and also the peculiar motor effects on voluntary muscle which nicotine was already known to produce.

Isolation of Acetyl-choline from Spleen Extracts.

Dr. Dale went on to describe the work of Loewi and others on the frog's heart as affording evidence of the peripheral release, during vagus stimulation, of a chemical substance transmitting the characteristic effects of vagus impulses, and suggesting the properties of acetyl-choline; and then he told of some recent work of his own and his colleagues on spleen extracts, using the spleens from freshly killed oxen and horses, in which a surprisingly powerful action of the choline type had been found. Here was an intensely active and unstable choline ester, naturally present in an animal organ, and in such proportion that the attempt to isolate it was a reasonable enterprise. Such isolation had just been completed by his colleague Dr. Dudley and himself, and they were now able for the first time to state that the substance was indeed acetyl-choline. It was not to be supposed that the finding of acetyl-choline in the spleens of certain animals had necessarily any significance as regards the spleen itself or suggested a true hormonic action of the substance. The identification was important chiefly for the reason that acetyl-choline, which first came to notice as an artificial substance, and had hitherto been known only as such, or as a product of plant metabolism, was now known to be actually a natural constituent of the animal body. Dr. Dale entered upon a discussion of certain hitherto disconnected physiological phenomena which reinforced the strong probability that here one was dealing with acetyl-choline itself, and not with some unknown substance having similar properties.

Effects of Organic Extracts.

In summing up the whole subject, the lecturer said that he had endeavoured to describe the part played in the control of circulation by four chemical agents which seemed to him to be the only ones sufficiently definitely known to warrant even provisional conclusions as regards their normal

functional significance. Evidence existed as to the effects of extracts from various organs of the body, artificially injected, or applied to isolated preparations of cardiac or involuntary muscle; but a great many of these observations could only as yet be put on record for future interpretation. There was evidence, for example, as to the effect of extracts from the right auricle or sino-auricular junction on isolated heart muscle. It had been suggested that some of the stimulating or restorative effect of such extracts on the rhythm of the muscle might be due to the presence of histamine. There was not yet sufficient evidence to justify the assumption that such an extract contained a "heart hormone." What was really needed was a system of criteria or postulates (comparable to Koch's celebrated postulates dealing with the etiological significance of a micro-organism), representing conditions which must be fulfilled before physiological significance was attributed to the effects produced by the artificial application of an organ extract. There was no hope, however, that any such criteria as could at present be suggested would be more generally applicable, or less liable to exception, than Koch's postulates had proved to be in their own sphere.

Scotland.

The General Election: Scottish Universities.

THE result of the election of three members of Parliament for the combined Universities of St. Andrews, Glasgow, Aberdeen, and Edinburgh was declared on June 10th as follows:

*John Buchan (C.)	...	9,959
*Sir George Berry, F.R.C.S.Ed. (C.) ...	...	9,262
*D. M. Cowan (L.)	...	6,698
Dr. James Kerr (Lab.)	...	2,867

An asterisk denotes that the candidate sat in the last Parliament. Sir George Andreas Berry has been one of the members for the Scottish Universities since 1922. He is Extra Surgeon-Oculist to the King in Scotland and a Past-President of the Royal College of Surgeons of Edinburgh.

Public Health in the County of Aberdeen.

In the fourth annual report, for the year ended December 31st, 1928,[1] Dr. H. J. Rae, medical officer of health to the county of Aberdeen, states that the statistics for 1928 were, on the whole, satisfactory. The number of deaths in the eight districts was 1,415, which corresponds to a death rate of 13.4 per 1,000 of estimated population, the same rate as prevailed in 1927. Compared with 1927 there was a decrease of 48 deaths from influenza and 30 from cancer, but there were 48 more deaths from circulatory diseases and 19 more from tuberculosis. There was a decrease in the incidence of scarlet fever—577 cases as against 603 in 1927—and a slight increase in the incidence of diphtheria, 109 cases being notified as against 93 in the previous year. Schick and Dick testing and re-testing, with subsequent immunization of those found to be positive, continued to be used as a preventive measure, but failing the employment of a special medical staff this work in the rural areas was of necessity sporadic in character. Dr. Rae found that while in scarlet fever active immunization might prevent the occurrence of return cases, the same could not be said of diphtheria. The fact that immunity conferred by injections of toxoid-antitoxin took from six weeks to six months to develop made this device useless in the prevention of return cases. The most alarming outbreak of infectious disease was a sharp, but fortunately limited, epidemic of infantile paralysis, which occurred chiefly in the Fyvie district; in all, thirteen persons were attacked by this disease, and one died. During the last three years there had been a considerable increase in the provision of new houses; in 1928 the number of new houses completed at December 31st was 149, and 70 were in course of erection; in 1927 the corresponding figures were 111 and 107. The maternity and child welfare scheme continued to expand, and it was satisfactory to report a decline in the notifications of ophthalmia neonatorum. The total number of births registered in the area was 2,629, as compared with 2,559 in 1927. The rate of infantile mortality was 63.5, as compared with 73.5 in 1927 and 75.5 in 1926; the Scottish rate for 1928 was 86, and in 1927 it was 89. The maternal mortality rate, however, was higher than usual, the case mortality being 47.8 per cent., as against 6.6 per cent. in 1927. The school medical officers had to deal with 26,000 children, and it was an alarming fact that about a quarter of the beginners required medical attention. The majority of defects had thus manifested themselves in the pre-school period, and were due partly to hereditary degenerative processes, and partly to malnutrition and after-effects of infectious diseases, such as measles, whooping-cough, and tuberculosis. Many children entering school were already suffering from late rickets, general debility, diseases of the ear, nose, and throat, mouth breathing, and decay of the temporary teeth. The sick child, in Dr. Rae's view, should not be looked on as an independent unit, but as one of a family, the work of the school medical officer and the child welfare medical officer merging into one. To safeguard the health of the child it would be necessary to extend the Insurance Acts to cover the dependants of insured persons, and to include the general practitioner in a comprehensive scheme for the prevention of disease. The dental treatment of school children was gaining so much in popularity that it was difficult for the dentists to visit all the schools during each year. Increasing attention was also being given to the treatment of eye defects, but there were a few parents who refused to allow their children to follow the oculist's advice. During the year under review the number of cases of phthisis notified—namely, 149—was the lowest yet recorded, though a greater number of non-pulmonary notifications (153) had been made than in any previous year with the exception of 1924. The death rate from all forms of tuberculosis was 97.07 per 100,000, and from pulmonary tuberculosis alone 71.2 per 100,000. The Scottish tuberculosis death rates were 97 per 100,000 from all forms of tuberculosis, and 69 per 100,000 from tuberculosis of the lungs—the lowest Scottish tuberculosis death rates yet recorded. Dr. Rae does not anticipate that the Local Government (Scotland) Act, 1929, will entail much alteration in the organization of the health services, but suggests that future hospital policy will have to provide a concentration of hospital accommodation for persons suffering from infectious diseases throughout the county. Presumably the Public Health Committee to be constituted under the Act would deal centrally with all public health matters, leaving, however, scavenging, water supply, and drainage in the hands of local committees.

Visit of American Doctors to Edinburgh.

Some sixty members of the Inter-State Post-Graduate Assembly of North America visited Edinburgh on June 3rd and 4th, spending the forenoons of both days in the Royal Infirmary. A clinical programme had been arranged by Mr. W. A. Cochrane and Dr. Stanley Davidson. On June 3rd Dr. Woodburn Morison conducted the party round the new radiological department, and gave a demonstration. Thereafter the members split up into sections. A medical clinic was given by Professor W. T. Ritchie, and a lecture-demonstration on irradiated milk, its preparation and uses, by Dr. Chalmers Watson. Mr. Henry Wade carried out operations for renal tuberculosis, renal calculus, and enlarged prostate. Professor John Fraser performed two gastrectomies, excision of the breast, and Spössel's operation for spastic paralysis. Professor D. P. D. Wilkie operated on cases of duodenal ulcer and carcinoma of the rectum. These interested in gynaecology were catered for by Professor R. W. Johnstone, and laryngologists attended Dr. J. S. Fraser's clinic. On June 4th Mr. David Lees spoke of the treatment of neuro-syphilis. Professor Edwin Bramwell gave a medical clinic, Mr. J. M. Graham lectured on perforations of the alimentary tract, and Mr. J. J. M. Shaw demonstrated cases. In addition, Mr. W. Mercer did a bone graft and an operation for ulnar paralysis, while Mr. W. A. Cochrane showed a series of patients who had been operated on for simple fractures, and also performed

[1] Fourth Annual Report by the Medical Officer of Health on the Health and Sanitary Conditions of the County of Aberdeen for the year 1928. Aberdeen: C. Cornwall and Sons. 1929.

an operation for severe flexion contracture of the hip following poliomyelitis. The afternoons were spent in excursions.

New Students' Hall of Residence in Edinburgh.

There has hitherto been little development of residential halls for students in Edinburgh, although many years ago Professor Patrick Geddes and the Town and Gown Association instituted University Hall on self-governing lines, and its three houses—Ramsay Lodge, St. Cuthbert's House, and Blackie House—have continued to flourish. Recently Mr. Thomas Cowan, LL.D., retired shipowner, gave a sum of £55,000 for a new residential hall for men students. His first gift of £15,000 was made in recognition of the excellent work of the students in the general strike. Some houses on the south side of George Square have been reconstructed and extended for the purpose, and now Cowan House is nearing completion, and will be ready for occupation at the beginning of the winter session. Mr. R. D. Maclennan, M.A., lecturer in philosophy, has been appointed warden. The present accommodation consists of 100 study-bedrooms, of which 23 can be shared by two students, along with dining room, common room, library, and tennis courts. The charge is from £13 to £23 per term of ten weeks. Permission to reside in residence during vacations may be given by the warden. Applicants must give two references, and preference will be given to applicants of Scottish, English, Welsh or Irish descent. A few members of the teaching staff may be admitted. The University Court is the ultimate authority in all matters relating to the residence, but provision is made for a house committee consisting of the warden and five of the residents.

New Mental Institution for Govan.

Caldwell House Institution for Mental Defectives, which has been provided by the Govan District Board of Control in order to fulfil the terms of the Mental Deficiency Act, was formally opened on June 6th. The purchase of the Caldwell estate, which extends to 230 acres, the reconstruction of the mansion house and outbuildings, and the erection of a water tank of 100,000 gallons capacity, have involved an expenditure of £40,000. At the present moment there is accommodation for 70 female and 25 male defectives, but further extensions in the shape of pavilion dormitories and special nurses' quarters will be necessary. Mr. W. G. Sharp, chairman of the Caldwell Committee, performed the opening ceremony, and referred to the seriousness of the problem of mental deficiency. In Govan parish there were approximately six hundred certified or certifiable cases, but, in his opinion, if there was a closer investigation on the lines of the Commission for England and Wales it would not be surprising if the numbers were doubled. Dr. Hamilton Marr, one of the Commissioners of the General Board of Control for Scotland, said that all defectives were capable of being educated and being made useful to themselves and probably to the community. The central point of such an institution was its school. On the other hand, the central point of an asylum was its hospital. Other speakers were Mr. John Nelis, chairman of the District Board of Control; Dr. A. S. M. Macgregor, medical officer of health for Glasgow; and Dr. H. S. Edington, president of the Royal Faculty of Physicians and Surgeons of Glasgow.

Selkirk Hospital Association.

At the second annual meeting of subscribers to the Selkirk Hospital Association, Provost Ballantyne, who presided, stated that the association was now in a satisfactory position. They had a good going concern in Viewfield Nursing Home, a regular income fairly well assured, and a fine freehold building practically paid for. The number of patients treated during the year showed how great was the need for such an institution in Selkirk and district. The endowment fund now amounted to £7,396. The total ordinary revenue had been £1,500, and the expenditure £954. It had been decided to have fixed charges, of 3s. per day for contributors and 4s. per day for non-contributors. There were some cases, however, which would have to be admitted without paying these charges, but this matter would be in the hands of the committee.

Ireland.

Post-graduate Course at Trinity College, Dublin.

The programme for the post-graduate classes which are held in the autumn of each year in connexion with the Medical School of Trinity College, Dublin, has now been issued. This year a comprehensive course starts on September 16th and ends on October 5th. Post-graduate instruction is given in medicine, surgery, midwifery and gynaecology, diseases of the eye, diseases of the throat, nose, and ear, diseases of the skin, orthopaedic surgery, genito-urinary diseases, pathology and bacteriology, bio-chemistry as applied to medicine, anatomy, therapeutics, pathology and the uses of radium, and electro-cardiography. Arrangements have been made whereby some of those attending the classes can reside within the College; women can be accommodated in Trinity Hall. Further information concerning these classes can be obtained from the Secretary of the Post-graduate Classes, School of Physic, Trinity College, Dublin.

Births and Deaths in the Irish Free State.

The births, 13,670 in number, registered in the Saorstat during the quarter ended December 31st last were equivalent to an annual rate of 18.8 per 1,000 of the estimated population, which rate is 0.1 below the average for the fourth quarter of the preceding ten years and 0.2 below that of the fourth quarter of 1927. There were 9,803 deaths, equivalent to an annual rate of 13.0, which is 1.5 below the average for the fourth quarter of the preceding decennium and 0.3 below the rate for the fourth quarter of 1927. Of the deaths, 956 (13 per cent.) were those of infants under 1 year, and 4,338 (45.7 per cent.) of persons aged 65 and upwards. The number of deaths of infants was equivalent to 68 per 1,000 births registered, as compared with 62, 61, and 56 for the preceding quarters. The 3,556 marriages registered during the third quarter of 1923 were equivalent to an annual rate of 4.8 per 1,000, the rate being 0.1 above that for the corresponding period of 1927, and 0.2 below the average for the third quarter of the preceding ten years. Of the total number of marriages, 3,249 were those of Catholics. The marriage rate among Catholics is 0.2 below, and that relating to other denominations 0.1 above the average for the third quarter of the ten years 1918–27. In Northern Ireland, for the last quarter of 1923, the births registered were equal to an annual rate of 19.1 per 1,000, in England and Wales to 15.7, and in Scotland to 19.0. In the same period the deaths registered in Northern Ireland were equal to an annual rate of 14.4, in England and Wales to 11.7, and in Scotland to 12.9.

School Inspection in County Derry.

The report of Dr. M. Matson, school medical officer to the Derry and Limavady Education Committee, for the year 1928–29, stated that 74 per cent. of the children on the rolls presented themselves for general inspection. By far the most common defect was decayed teeth, from which 36 per cent. suffered more or less; 25 per cent. suffered from enlarged tonsils and adenoids, and 9 per cent. from defective vision. Defective speech was more common than defective hearing. There were no cases of definite pulmonary tuberculosis, but a few suspicious cases were referred to their own doctor for observation. Many children were anaemic; 316 were verminous. The school nurse visited 582 children at their homes, and paid 297 revisits to schools; subsequent to the medical inspection she noticed a great diminution in the verminous cases. The majority of the anaemic cases had improved. Many children were wearing and deriving great benefit from the free spectacles: 20 had their tonsils and adenoids removed. Very few of the school buildings were altogether suitable or in good order. Most of the voluntary schools required repairs and new equipment. Seven schools were somewhat overcrowded; two had no playground; in ten the ventilation and lighting were inadequate; four were insufficiently heated; six had either insufficient or no cloakroom accommodation. One

school had no water supply, while at fourteen others the water had to be carried from an inconvenient distance. Two schools had no closets, and at sixteen others the closets were unsuitable in type or in extremely bad repair. The interiors of many of the voluntary schools were depressing.

England and Wales.

Prevention of Mule-Spinner's Cancer.

INVESTIGATIONS carried out under the auspices of the Manchester Committee on Cancer on the part played in the production of cancer by the lubricating oils used in cotton mills have confirmed previous findings on the carcinogenetic power of various oils, and yielded valuable information on the concentration in them of the cancer-producing principle. The committee, in its annual report for the year 1928, states that search for the actual cancer-producing substance is proceeding satisfactorily, having been so concentrated in a pure artificially made tar that a 5 per cent. solution of this substance has been shown to be more powerful than shale oil, the most dangerous of all commercially used oils; furthermore, two pure compounds of known chemical constitution have been proved capable of producing tumours. Investigations are being conducted to determine the factors which change a non-carcinogenic into an active carcinogenic substance. No carcinogenicity has been demonstrated in bitumen; pitch, on the other hand, has proved to be very active as a cancer-producing agent. Important investigations have been undertaken with a view to destroying the cancer-producing power of certain oils, so as to render them safe for industrial use. Partial success has attended some of the methods which have been employed, one particularly having resulted in the production of a purified oil which, when subjected to vigorous tests, failed altogether to produce cancerous growths. Representatives of the cotton industry who have compared this oil with the crude untreated oil have reported that its lubricating power is unimpaired. The committee is therefore able to hold out the hope that before long it will be possible to put on the market an oil which fulfils the needs of industry, above all, cotton spinning, and is yet quite safe to the workers. Before taking such definite action, however, it desires to be sure of its results, and believes that considerable confirmatory work will have to be carried out. Meanwhile the committee recommends the use of lubricating oils which contain no shale oil.

The Home Ambulance Service.

The responsibility of the police in regard to the removal of persons found injured on the roads is stressed by the Joint Council of the Order of St. John and the British Red Cross Society in its report for the quarter ended March 31st. The Home Office returns have once more drawn attention to the increasing number of road accidents, 156,024 persons having thus been killed or injured in 1928, or over 12 per cent. more than the number in 1927. The police, suggests the council, may meet their responsibility by initiating their own ambulance service, or by making use of the vehicles of local authorities or of those belonging to the Order and Society. Already many, if not all, of the home service ambulances work in close association with the police. So long, however, as there is an existing service which can be relied on to meet calls at any time of the day or night a separate police ambulance service, especially in country districts, would seldom be economical or advantageous to the public. The council suggests, further, that county representatives and those in charge of ambulance stations should, in view of the ever-increasing scope of their work, consider the question of making a satisfactory arrangement with the police authorities in their own areas. The police, it points out, are empowered to bear certain expense in regard to this work, and would probably be fully alive to the advantage of supporting by a small subsidy or the payment of a small fee an existing service already available day and night. The Order of St. John is engaged in preparing specifications for first-aid huts which can suitably be erected and equipped by the roadside at a reasonable cost. Several huts of various patterns have already been erected about the country, and have proved of real service in treating road accidents. There can be no doubt that an extension of this work will help to minimize the consequences of injuries. The council is able to report that during the quarter no fewer than 19,109 patients were carried in the home service ambulances, and 9,742 in the affiliated ambulances, bringing the total number of cases carried to March 31st up to 762,339.

Remuneration of Coroners.

The London County Council is proposing to increase the remuneration of coroners in view of the additional duties devolving upon these officers in consequence of the Act of 1926. It is pointed out that coroners are empowered by that Act to order post-mortem examinations to be made in cases in which no inquest is held, and as a result they now decide, on their own responsibility, large numbers of cases in which, under the old procedure, inquests would have been held. During the first eight months in which the Act was in operation, 1,573 such cases were dealt with by London coroners. Further responsibilities are imposed upon them in connexion with the holding of inquests without a jury, and in connexion with disagreements by juries as to their verdicts. Coroners of the County of London are required to have both legal and medical qualifications, and it is considered that the increase in the responsibilities attaching to the position warrants an increase in allowances of £100 a year with effect as from January 1st last. The result will be to raise the total remuneration paid to the seven coroners by the Council from £9,715 to £10,415 a year.

Correspondence.

THE DEFINITION OF RHEUMATOID ARTHRITIS.

SIR,—The article by Dr. A. H. Douthwaite on some aspects of the treatment of rheumatoid arthritis (June 8th, p. 1035) raises a very important question with reference to the nomenclature of this condition. The writer of the article describes very clearly three types of cases, loosely termed "chronic rheumatism"—namely, (1) rheumatoid or atrophic arthritis, (2) infective arthritis, (3) osteo-arthritis or hypertrophic arthritis—and one would conclude that these types are included under the common designation "rheumatoid arthritis." According to this view, which is shared by many other authorities, rheumatoid arthritis is a group denomination; as a rule, however, the last-named condition—osteo-arthritis—is relegated to a category by itself.

While agreeing wholeheartedly with Dr. Douthwaite in recognizing three distinct types of so-called chronic rheumatism, I cannot help thinking that a great deal of the confusion with regard to chronic rheumatism is due to the loose manner in which the term "rheumatoid arthritis" is used. Is it not possible to arrive at some sort of general agreement as to the precise limitations of the term? I would propose that the designation "rheumatoid arthritis" be definitely confined to the first of the three clinical types Dr. Douthwaite describes:

"... a disease occurring largely in females of reproductive age and characterized by little or no pyrexia, low blood pressure, and unstable pulse rate, scattered pigmentation of the skin, on a basic waxy pallor, generalized wasting in addition to pronounced atrophy of the muscles about the affected joints, visceroptosis, hypochlorhydria, exaggerated tendon reflexes, and symmetrical swellings of smaller joints, particularly those of the fingers. The skin over the affected articulations is pale and atrophic, and local tenderness to pressure is never a striking feature. With the exception of increased translucency, bony change is absent for months or years."

Dr. J. A. Glover, in the Ministry of Health report on chronic arthritis (page 5), also refers to this type of case as follows:

"... the singularly acute and intractable form which occurs for the most part in quite young women undoubtedly merits some special mention. In this variety the initial attack is usually particularly severe and the resemblance (before described) to rheumatic fever unusually close. A recognizable focus of infection is

seldom seen in this form of the disease, and little or nothing is known of its etiology. It usually ends in the pathological variety known as 'atrophic.' It is of great importance from one point of view, in that, from its peculiar intractability to treatment, it has in no small measure helped to produce the pessimistic frame of mind with which the majority of the profession and laity alike have been wont to regard all chronic arthritis, many forms of which are, fortunately, much more amenable to treatment."

Although the two descriptions do not quite coincide there can be no doubt that both authorities are referring to the same condition. If it could be agreed that the term "rheumatoid arthritis" should be strictly limited to the above-described condition as it occurs in women of reproductive age, current ideas as to the terminology of chronic rheumatic affections would undergo a much-needed clarification. Such a limitation of the term would, of course, imply that the condition is wholely confined to women. Any joint condition in the opposite sex which in any way approaches it could quite well be described as atrophic arthritis, infective arthritis, or focal arthritis. Of course, there is a type of joint affection due to the presence of some focus of infection which arises in both sexes, but the term "rheumatoid arthritis" should not be used in that relation. It appears to me that if a definite sex incidence is ascribed to the condition in question, the gain in lucidity of description would amply compensate any problematical loss in accuracy.—I am, etc.,

London, W.1, June 7th. MATTHEW B. RAY.

VITAMIN A IN INFECTIVE CONDITIONS.

SIR,—I am sure all students of medicine will feel on reading in your issue of June 1st (p. 924) the paper by Professor E. Mellanby and Dr. H. N. Green that a new vista of rich promise has been opened out by their work. Whether their efforts have solved the hitherto elusive problem of streptococcal septicaemia or not, it seems clear that their very interesting preliminary experimental work will remain as a permanent milestone on the road of scientific progress. My object in writing, however, is not to eulogize this brilliant work, but to record briefly two cases in which radiostoleum (a product containing vitamins A and D) was used as a result of their previous paper in the *British Medical Journal* of October 20th, 1928 (p. 691).

Case 1.—A medical man developed a febrile attack last February, the temperature on one occasion reaching 105° F. A blood culture yielded a pure growth of *B. proteus*. He had frequency of, and severe pain on, micturition; there was pus in the urine and, later, some albumin in centrifuged specimens. His pulse at one stage was over 120, and of such a character as to cause grave anxiety. Prior to this febrile attack he had suffered for some time from more or less annoying dyspeptic symptoms. In addition to merely symptomatic treatment, he was given radiostoleum capsules and inoculations of an autogenous vaccine in very small doses. After one slightly larger inoculation some aggravation of the patient's symptoms appeared to result, and the vaccine was discontinued; but at this stage his serum agglutinated strongly the bacillus, which had been isolated. He eventually recovered. There was, however, nothing dramatic about the result, but it leaves the impression that radiostoleum is worth a trial in infections of this type, which are presumably of intestinal origin.

Case 2.—A patient suffering from very intractable furunculosis was given radiostoleum two months ago and inoculations of an autogenous vaccine. His condition still remains unsatisfactory.

One hopes that in our endeavours to ascertain the therapeutic value of vitamin A some attempt may be made to identify the exact nature of the infection in each case, as it seems *a priori* improbable that all patients suffering from infective conditions are predisposed to infection by vitamin deficiency.—I am etc.,

Manchester, June 5th. J. STAVELY DICK.

RELATIONSHIP OF ALASTRIM (VARIOLA MINOR) TO SMALL-POX (VARIOLA MAJOR).

SIR,—Dr. E. G. Fenton (June 8th, p. 1060) takes the view that variola minor and variola major are one and the same disease, and he advances the theory that the mild nature of variola minor is "entirely due to the fact that vaccination has now been extensively practised in Great Britain for over a hundred years," and has in consequence created a sort of hereditary immunity comparable to the immunity to malaria enjoyed by certain native races. Such a theory is, of course, attractive, as it affords a simple explanation of the remarkable mildness of present-day small-pox, while at the same time paying a graceful tribute to vaccination. I have heard it seriously propounded on many occasions. Unfortunately, a very little reflection will show that the theory is quite untenable. The chief arguments against it are as follows:

1. When variola minor invades an unvaccinated community like the city of Leicester (where compulsory vaccination was abandoned over forty years ago, since when 90 per cent. of the children born have not been vaccinated) it should, if the theory were sound, show a greater severity than in places where vaccination has been normal. Forty years without vaccination should surely be enough to weaken this "hereditary" immunity. But what are the facts? Variola minor is just as much variola minor in Leicester as elsewhere. During the past twenty-five years there have been some 369 cases of small-pox in Leicester without a single death. The last fatal case occurred in June, 1904. This may come as a surprise to Dr. Fenton, and to many others also; but it is nevertheless true.

2. On the other hand, when variola major appears in any part of Great Britain it quickly reveals its true nature in spite of Dr. Fenton's postulated "hereditary" immunity. There have been several instances of this in recent years, the latest being the *Tuscania* outbreak. Hereditary immunity did not do much to reduce the severity of the disease in these outbreaks.

3. Lastly, there is no true analogy in the immunity of native races to malaria. Such immunity is the result of natural selection, and is easily understandable; but what Dr. Fenton postulates is a hereditary immunity resulting from an *acquired* artificial immunity acting through some four generations. I think that any authority on heredity would say that there is no more likelihood of such a result than that the racial custom of circumcision should shorten the length of the prepuce. For, after all, "there's a divinity that shapes our ends, rough-hew them how we will"!—I am, etc.,

Leicester, June 8th. C. KILLICK MILLARD.

APPARENT RECURRENCES OF SCARLET FEVER.

SIR,—I was especially interested in Dr. Kelleher's article on recurrences of scarlet fever, in your issue of June 1st (p. 985), because I have seen one very unusual recurrence of the disease in the case of two brothers whom I treated.

In May, 1927, I was called to see a boy, aged 11, who had all the typical symptoms—erythema, severe throat symptoms, strawberry tongue, circumoral pallor, and a temperature of 102°. On my informing his mother that he had scarlet fever, she immediately protested that he had had similar attacks during the month of May in two preceding years, and that on each occasion he had been treated as a case of scarlet fever. I was dubious of this statement and did not pay much attention to it, especially when six days later a young brother, aged 3, developed typical scarlet fever. Desquamation occurred in both cases and the disease ran the usual course.

In May, 1928, I was called to see the same boy, who again had every symptom of typical scarlet fever. I asked my partner and the medical officer of health to see him, and both agreed with my diagnosis. Five days later the same young brother developed it, and both again followed the usual course, including considerable desquamation. In both years the boys had been in contact with scarlet fever at school, and there were numerous cases of it in the locality. This year both boys escaped.

I think there is no doubt that these were true recurrences.—I am, etc.,

Harrow, June 6th. H. P. WALSH, M.B., B.Ch.

ANAESTHESIA FROM THE SURGEON'S STANDPOINT.

SIR,—The article by Mr. Basil Hughes on progress in anaesthesia from the surgeon's standpoint (May 18th, p. 897) interests me, but from the anaesthetist's standpoint. It certainly shows that some effort is being made to advance, though it is extremely small and slow. One reason for this is the common belief that anyone is capable of giving an anaesthetic, and that no special knowledge is necessary. Taken generally, fees are in proportion to this idea, and therefore medical men are not encouraged to specialize in this branch of medicine. I have seen Mr. Basil Hughes operate, and can therefore appreciate why he is so partial to local and spinal anaesthesia.

The avertin anaesthetic (rectal) which he mentions has certainly given good results on the operating table, and afterwards, according to the report from St. Luke's Hospital, Bradford. The number of cases quoted—namely, 100—is very small, though, in my opinion, the way it is used there for a very light anaesthesia, in combination with 0.5 per cent. novocain solution locally, tends to safety.

The experience of the German originators has not been quite so happy. Killian, in 13,000 cases, mentions four deaths from ulcerated bowel (a difficulty which I believe is said to be overcome now), and there have been other deaths. Drs. Blomfield and Shipway, in the *Lancet* (March 16th), report 198 avertin anaesthetic cases, with two deaths. I know the cases were bad ones, but when this death rate is compared with the 1 in 2,000 death rate from chloroform (admittedly a most poisonous drug), I think there will have to be much more work done before the use of avertin becomes general. There is, however, no doubt of its convenience from the surgeon's standpoint.

Mr. Basil Hughes is rather hard on inhalation anaesthesia, for it has some valuable advantages—for instance, control. With spinal and avertin, or rectal ether, once the drug has been given the anaesthetist has lost all control. With the inhalation anaesthetics, on the other hand, a considerable amount of control remains, especially with nitrous oxide and oxygen, which is removed from the patient in about twenty seconds at will. If Mr. Basil Hughes had tried out nitrous oxide under good conditions he would have found his mortality decreased still further, and all the advantages of post-operative comfort and absence of vomiting for his patients. The experience in the United States of America bears out this view.

Gas and oxygen is not used extensively in England because of the harm that Boyle's apparatus and its modifications have done. This apparatus is misnamed in being called a gas and oxygen apparatus; really it is an ether apparatus for use in conjunction with gas. It is because anaesthetists try to give gas and oxygen with this or similar apparatus that we get experiences like the following:

> I was asked to give an anaesthetic for an old patient of mine who was to undergo an operation for panhysterectomy. I proposed to give gas and oxygen, but the surgeon said that in his experience this anaesthetic was a failure. I said, "It won't be a failure this morning, and, moreover, the patient won't be sick afterwards." After the operation, which took an hour and a half, the surgeon said, "Well! you've converted me; the anaesthetic has been excellent, and I had no trouble to do my work." The patient never vomited, nor was she ill in any way; she made a perfect recovery.

I do not claim to be specially clever, but I had an apparatus which was reliable and would do the job. I could not have done it with a "bubble bottle," because the oxygen control is not within 15 to 20 per cent. If I had to work with such a machine I should give it up, and agree with those who say that nitrous oxide and oxygen is impossible for abdominal work, and not very suitable for any long operation.

During the past twelve months I have used gas and oxygen for twelve hysterectomies, many gall-stone cases, several gastro-enterostomies, and any number of appendix cases. There have been no deaths. Given a careful surgeon there is no reason at all why nitrous oxide and oxygen, with its almost negligible mortality and morbidity, should not be used for every operation that is within the range of modern surgery. With the "bubble bottle" apparatus it is even necessary to use ether for an empyema case; but with a gas apparatus, with proper control, that would be unthinkable. I sincerely hope that more of our anaesthetists and surgeons will look closely into this matter, especially the younger ones.—I am, etc.,

Doncaster, June 7th. E. J. CHAMBERS.

"ANTIVIRUS" THERAPY.

SIR,—In your issue of May 25th (p. 955) is published a report of a paper on vaccine therapy by Professor Besredka, which was read at the annual general meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine. In view of the considerable criticism which this paper aroused, perhaps you will allow me to make a few observations.

In the first place, it would seem from the report that the terminology used in the paper was confusing. The terms "vaccine" and "antivirus" appear to have been used throughout as if they were synonymous. But the term "vaccine," as usually understood, implies a suspension of dead bacteria prepared from a young culture, whereas Besredka uses the term "antivirus" to denote an inhibitory substance produced in an old broth culture.

It is unfortunate that the term "vaccine" employed in the paper was not more clearly defined, but, be that as it may, there seems no doubt from a laboratory point of view that filtrates from old broth cultures do possess remarkable inhibitory power; my own experiments lead me to believe that this phenomenon is not due to exhaustion of food materials, or to production of waste products. On the clinical side I am not qualified to speak, but I would refer to a paper by Buchanan[1] which was abstracted in a recent issue of the *British Medical Journal* (*Epitome*, April 13th, para. 373), and which gives an impressive list of cases, all suppurative or inflammatory conditions, in which broth filtrates were used with remarkably good effect.

My own view is that these filtrates act as fairly powerful antiseptics on bacteria such as staphylococci in purulent lesions, without in any way harming the body cells. Whatever may be the immunological theory underlying this action, the method seems worthy of extended clinical trial, and it would be unfortunate if the criticism which Besredka's paper evoked should tend to discourage further trial of antivirus therapy in practice.—I am, etc.,

Barnet, June 5th. R. F. HUNWICKE, B.Sc.

NATURAL AND ARTIFICIAL FOODS.

SIR,—Living somewhat off the beaten track, we, in the northern parts of Western Australia, get a mail but once in two months, and so I have only recently seen the *Journal* of December 15th, 1928, containing an article by Mrs. Mellanby and Dr. Pattison. I judge from it that the breakfast-table conversation of the future will be: "Tommy, have you taken your radiostol?" "Don't want no radiostol—want an apple."

Personally I don't know whether radiostol has any effect on the teeth or not; what I do know is that in England and America, where denatured or so-called refined cereals are eaten to the total exclusion of the natural grain, dental caries is increasing by leaps and bounds—so also are cancer and other diseases. In Western Australia, where white flour is in common use and the soil is deficient in calcium and phosphorus, it is quite common to find persons under 20 years of age without a natural tooth in their heads. I remember one poor little chap, aged 5, without a tooth showing, and the 6-year molars were irrupted decayed. That is one side of the picture.

Since 1900 I have lived in South Africa, West Africa, India, and now Australia. In Sierra Leone, when I was there, the natives lived on natural grain, fish, and game. There was no milk; owing to the tsetse fly no domestic animal could live on that coast. In South Africa the staple diet consisted of mealies, the millets, game, and milk. In the Punjab the staple diet is unleavened bread made of atta or whole-grain wheat flour, curried vegetables, dhal with a little ghee or clarified butter, and sour milk; they also eat a good deal of ghura or unrefined sugar as it comes from the cane, and, in the season, chew sugar cane. In the northern parts of Australia the aboriginal natives toil not, neither do they spin, but live on roots, fish, game, and, in the wet season, on beef. To those who say meat is bad for us I would mention that recently three natives were brought before me for cattle killing, and it came out in evidence that not more than fifteen natives had, in four days, killed and eaten three bullocks; the bullocks, or those parts of them eaten by aboriginals, would weigh about 600 lb. a carcass.

To return to the food question. All these people living on the edge of or outside civilization have one, and only one, food factor in common, and that is the consumption of

[1] *Journal of the Medical Association of South Africa*, January 5th, 1929, p. 37.

the whole grain of their cereal food. Dental caries is rare among these people, and also deformed jaws. I estimate that I examined the mouths of two or three thousand natives in India of military age and of all castes below the fighting caste. At the end of the dry season, when green food was unprocurable, I noted that pus could be expressed from the margin between gum and teeth, but with the advent of green food this condition cleared up; dental caries was negligible. I presume that all medical men know that white flour is made by sifting out the germ and bran of wheat; further, that the germ and bran contain the vitamins and vegetable salts of metals necessary both for the life of the wheat and for animal life. I wish to stress the fact that the salts contained in the wheat germ and bran are absolutely essential for animal life, and, further, that they are necessary for the complete digestion of the starch and gluten of white flour. In my opinion, whenever the fruits of the earth are contained in a palatable skin, that skin should be eaten, since it is required for the complete digestion of that fruit. I was taught, when learning physiology, that certain salts were necessary for life; presumably, the same truth is still taught. Why, then, does the medical profession allow, without protest, the miller to reject as pig food the bran and germ of wheat? I believe the answer is that the germ and bran are indigestible. A more fallacious argument or greater perversion of the truth was never uttered. If whole wheatmeal bread is not properly masticated, of course it is not digested; thoroughly masticated, it is one of the best of cures for dyspepsia and constipation that I know.

To the dietitians and others who deal in calories, to veterinary surgeons, stock-breeders, and others who eat denatured grains, I put this question: If denatured grain is best for you, surely it must be best for laboratory and stud animals; why not feed them on it? It is time the medical profession paused and thought before going into the virtues of radiostol and other vitamins. Our ancestors, and millions of people of to-day, living on foods as God gave them, and knowing nothing of vitamins, vegetable salts, calories, etc., maintained and maintain themselves in rude health, their only guide being their appetite. Remarks to the effect that a teaspoonful of gravy a day will supply this, a teaspoonful of yolk of egg will supply that, and one lettuce leaf a fortnight will supply the other thing are listened to with grave attention by the public when uttered by eminent medical men. Such remarks are, to say the least, misleading.

Before the children of Israel crossed over into the Promised Land, Moses harangued them and made the following promise: "Wherefore it shall come to pass, if ye hearken to these judgements, and keep, and do them, that the Lord thy God shall keep unto thee the covenant and the mercy which He sware unto thy fathers. . . . And the Lord will take away from thee all sickness, and will put none of the evil diseases of Egypt, which thou knowest, upon thee; but will lay them upon all them that hate thee." The quotation at first sight seems irrelevant, but I take it to mean, among other things, that simplicity of feeding was to continue. Wherefore, I ask the heads of the profession to pause and ask themselves: Where are we leading the nation? The cause of dental caries is undoubtedly the lack of cereal salts and hard chewing; the diet of grain-eaters proves this. It is more than a fifty-fifty chance that cancer is a food-deficiency disease, and similarly with acidosis, beri-beri, pellagra, and so forth.

I repeat: In which direction are the heads of the medical profession going to lead—back to perfect food as God gave it, and health, or onwards to vitamins, denatured foods, and disease? The laity will follow and trust us. Which is it to be—the health and prosperity of the British nation, or the death of the nation and its replacement by a whole-grain-eating coloured people? The world is outside the laboratory and will not wait for the evolution of the large-brained, jawless, and puny-bodied being who will live on tabloids.—I am, etc.,

F. W. COTTON.
Lieut.-Colonel R.A.M.C.(ret.).

Wyndham, Western Australia,
April 12th.

Obituary.

SIR CHARLES O'BRIEN HARDING, M.R.C.S.,

Past-President, Sussex Branch, British Medical Association, and thrice Mayor of Eastbourne.

SIR CHARLES O'BRIEN HARDING, who died at Eastbourne on June 7th, aged 70, was the son of Dr. J. F. Harding. Educated at Epsom College, he proceeded for his medical studies to the Sussex County Hospital and to St. Bartholomew's Hospital, obtaining the diploma of M.R.C.S. in 1883 and the L.R.C.P. in 1886. He was house-surgeon at St. Bartholomew's from 1883 to 1884, and then for a short time was a surgeon with the Orient Steam Navigation Company. He went to Eastbourne to practise in 1891.

Although enjoying a considerable practice, Sir Charles Harding will be remembered locally mainly on account of his extraordinary interest in municipal and other public affairs in Eastbourne. His record of service in public life is probably unsurpassed by that of any other medical man. After five years' practice in Eastbourne he was elected to the town council, and remained a member of the council, first as councillor and later as alderman, until early in 1929, when he resigned his position as alderman on account of failing health. He first served as mayor of the borough in 1902–3; he was again mayor from 1915–20 during the most difficult parts of the war years, and again in 1924–25. His services were so untiring and successful, particularly as mayor during the war, that a knighthood was conferred upon him in 1920. On the borough council his interests were very wide. He was particularly valuable in connexion with the sanitary work of the town. He also occupied at different times the chairmanship of the Watch Committee, the Finance and General Purposes Committee, and the Education Committee, as well as that of the Public Health Committee. He probably gave his most conspicuous service as chairman of the Finance Committee; his speeches as chairman of that committee, and particularly at the times of the making of the rates, will always be remembered for their remarkable lucidity, the multitude of figures regarding the finances of the borough being quoted without the aid of notes. Not content with his membership of the Eastbourne Borough Council, he served also as a member of the East Sussex County Council until Eastbourne became a county borough. In 1903 he was made a justice of the peace, and he also received the very unusual honour of being made a freeman of the county borough.

Sir Charles O'Brien Harding's devotion to municipal work did not end his activities. He was chairman of the Princess Alice Memorial Hospital, with the management of which he had been actively associated for many years. He was chairman of the Queen Alexandra Cottage Homes, and deputy chairman of the Eastbourne College Council. He was for a time in the R.N.V.R. as a lieutenant commander. He was president of the Eastbourne Horticultural Society, a director of the local building society, and also a director of the Eastbourne Waterworks Company. In fact, there were few activities in Eastbourne in which he had not a very active share. If anything of importance was to be undertaken in Eastbourne one of the first steps was to get Harding to act either as president or chairman, or in any case to take a leading part in the movement. All Freemasons will remember him as being especially well known in the craft. For a long time he was Director of Ceremonies for the Province of Sussex, and a Past Grand Master in the Mark degree. Only recently he had a beautiful testimonial given him for presiding over the Mark Mason Charity Festival. He was for many years an active member of the British Medical Association, serving as vice-chairman of the Eastbourne Division in 1907 and chairman in the following year, and remaining a member of the Executive Committee until 1916. He was president of the Sussex Branch in 1923–24, and was elected vice-president in 1927.

It was a very great advantage to Eastbourne that Sir Charles O'Brien Harding settled there and gave such valued service as a citizen. It is unfortunate that, as a rule, medical men have not more time to devote to municipal

service. The universal sense of loss which is felt in Eastbourne is a testimony to the service he gave in practically every direction. Besides the many people who have lost a great friend, the town as a whole is in mourning for the death of one of its most active and useful citizens.

While at Bart's Harding was a renowned Rugby footballer, and in his time played also for Middlesex and England. His interest in sport did not end when he settled in Eastbourne. He was on the committee of the Eastbourne Cricket and Football Club for many years, and acted for a time as its treasurer; he was also influential in resuscitating Rugby football in Eastbourne. The high regard in which his colleagues and fellow students held him may be judged from the fact that he was the only country general practitioner who took the chair at a St. Bartholomew's Hospital past and present dinner. The serious epidemic of influenza during the past winter claimed him as one of its victims; he never thoroughly recovered from his attack, and died of heart failure.

W. G. W.

SIR WILLIAM FAIRBANK, K.C.V.O., M.R.C.S.,

Honorary Surgeon-Apothecary to His Majesty's Household at Windsor.

WE regret to record the death, in his seventy-ninth year, of Sir William Fairbank, which took place on June 10th at his home at Windsor.

After receiving his early education at the Forest School, Walthamstow, William Fairbank entered, in 1868, as a medical student at St. Bartholomew's Hospital, where he was dresser to Sir James Paget; in 1872 he obtained the Licence of the Society of Apothecaries, and was admitted a member of the Royal College of Surgeons of England in the following year. In 1875, having completed an appointment as resident medical officer to the Royal Albert Infirmary, Wigan, he went as house-surgeon to the Rotunda Hospital, Dublin, and in 1877 became a licentiate in midwifery of the Royal College of Physicians of Ireland. In 1880 he was appointed surgeon-apothecary to Queen Victoria's Household at Windsor, and surgeon to Prince and Princess Christian, in place of his elder brother, Dr. Thomas Fairbank, who had just died suddenly. He then became in turn surgeon-apothecary at Windsor to Queen Victoria, to King Edward, and to King George.

Sir William Fairbank held a number of hospital and public appointments. For many years he was surgeon to the Windsor Royal Infirmary, being at the time of his death honorary consulting surgeon to its successor, the King Edward VII Hospital; he was local consulting physician to the Royal Ventnor Hospital for Consumption; chairman and president of the Royal Albert Institute at Windsor; examiner, and for thirty-nine years lecturer, to the Order of St. John of Jerusalem; a member of the Berkshire County Council, and from 1919 to 1920 mayor of Windsor. In recognition of his many services he was created M.V.O. in 1911, and promoted C.V.O. in 1921 and K.C.V.O. in 1924. In 1921 Fairbanks was a member of the delegation of British mayors who visited the devastated areas of France, and after Windsor had adopted Hardecourt-aux-Bois he raised funds for the reconstruction of the village, which afterwards he visited every year. In appreciation of his efforts the inhabitants of the village renamed after him their square and main street.

Sir William Fairbank married in 1879; he is survived by two sons and three daughters.

DR. JOHN BROWN, who died near Capetown on May 7th, in his eighty-sixth year, received his medical education at Aberdeen University, where he graduated M.D. (with honours) and C.M. (highest honours) in 1863. After spending ten years in Wynberg, Cape Colony, where he built up a successful practice, he returned to Edinburgh, and became demonstrator in anatomy at the University. In 1877 he took the diploma of public health, Cambridge, and in 1878 the Fellowship of the Royal College of Surgeons of England, and a degree in public health at Edinburgh. We are indebted to Dr. Athelstane Nobbs for the following appreciation: So well equipped was John Brown that he might successfully have invaded Charlotte Square, or come South to the purlieus of Cavendish Square, but he elected to work among the workers of Lancashire, and became junior partner to a Dr. Briggs in Burnley. In due course he became the senior partner when a certain brother Aberdonian, one James Mackenzie, became the junior—Brown being the surgeon, as it were, and Mackenzie the physician of the partnership. There can be no doubt that the man who later was to become the acknowledged master of the science of cardiology benefited by this early collaboration, and to the end Sir James Mackenzie, as he became, and his old senior, whose partner he had been in Burnley for twenty years, were the closest friends. John Brown, who, by the way, was a cousin of his namesake, the author of *Rab and His Friends*, had married a daughter of a former Premier of Cape Colony, and when he retired from practice, shortly after the South African war, returned to the Cape, but never to idleness. He leaves behind him the memory of one of God's good men, absolutely straight and humane, a scholar void of pedantry, with the capable hands of the ideal surgeon.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on June 8th the following medical degrees were conferred:

D.M.—G. L. Evans.
B.M.—R. M. J. Harper, D. C. Shields, M. V. Bhajekar, H. G. Wells.

UNIVERSITY OF CAMBRIDGE.

DR. R. A. WEBB has been appointed University Demonstrator in Pathology, and Messrs. G. Anrep and H. E. Tunnicliffe University Demonstrators in Physiology.

At a congregation held on June 8th the degree of Bachelor of Medicine (M.B.) was conferred on R. Gallimore.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—*†C. F. Cosin, *†E. A. Hunter (University medal), *†A. L. Light, *†E. G. M. Palser, *†S. F. Russell, *†H. A. H. Selbourne, *†C. E. W. Wheaton, Lucy E. Arthur, Mabel A. Baker, C. G. Bowen, Annie G. Busher, E. C. B. Butler, Alison M. Clark, Rosa O. J. Clark, S. L. A. Clarke, Joan C. Clatworthy, E. S. Cooksey, Hilda C. Dean, C. G. de Couilhard, V. P. de Zoysa, C. J. Donelan, D. E. Dunnill, Dorothy V. Dunolly, A. M. Easton, A. C. Elkin, C. N. Evans, G. S. Ferraby, Kathleen E. Gambrell, L. Gordon, D. P. Gray, Bridget S. P. Gurney, C. E. Hagenbach, Emily M. Hall, H. N. W. Harley, R. L. Harward, F. F. Hollier, C. F. Howes, E. C. H. Huddy, W. F. Hudson, H. E. James, P. Kaplin, D. W. S. Kaye, R. J. Krichefski, S. C. H. Lane, A. J. C. Latchmore, I. B. Limbery, G. H. Livingstone, W. S. McConnell, J. V. Macgregor, M. L. Mistri, Anna P. Montgomery, Jocelyn A. M. Moore, Joyce Morgan, D. T. E. Morris, C. B. Nicholson, C. G. MacM. Nicol, C. G. Paine, Keren I. Parkes, C. C. Pether, A. P. Pettigura, C. B. Picken, Betty J. W. Pilsworth, G. L. S. Plumbly, H. W. A. Post, I. Preiskel, K. H. Pridie, E. I. Puddy, W. G. Richards, Marjorie E. Roberts, I. M. Robertson, R. D. Robinson, Janet M. Roche, A. P. Ross, A. S. D. Russell, Beatrice A. Savill, J. E. Schneider, E. M. Sharples, D. Shaw, C. G. Sinclair, N. Sinnadurai, E. J. J. Smith, P. A. M. Soutter, R. B. Sugden, A. R. Thompson, F. S. Thornton, Decima M. Tracey, Frances J. Vinter, Nora W. Wamsley, A. J. Watson, S. A. Wickramasinghe, P. Wiles, W. A. Wilson, A. Wiseman, E. A. Wood, Joyce R. Woods, Mary Worthington, T. C. Yip, E. A. Young.

Group I.—Ellen M. Barnes, J. N. Bhada, C. V. Bloom, W. E. R. Branch, Eileen A. Chennell, Mabel J. Cooke, W. V. Cruden, Catherine Day, R. F. Fidler, Alice E. N. Gilby, D. R. Griffith, E. Grundy, F. R. Gustarson, G. F. Harrison, E. F. Hewlitt, J. F. L. King, G. Lee, Dorothy M. Lufkin, Dorothy F. McIntosh, T. H. Negus, A. T. Pagau, L. M. J. A. Pilot, J. C. Saldanha, C. P. Scott, Mary Sconloudi, Mary E. Sharp, R. Shelley, A. G. Sigay, Marjorie V. N. Sudds, K. G. Sugden, C. B. V. Tait, L. E. Vine.

Group II.—A. M. Boyd, Bertha A. Briant, Lilian P. Edwards, H. K. Evans, R. Evans, B. M. Fonseka, Ruth C. Gallotly, W. F. Hall, Margaret L. Hamburger, C. B. M. Hoggs, R. A. King, K. E. Lane, E. P. E. Laurent, A. Levy, F. J. G. Lishman, F. W. Martindell, R. Oliver, E. Purvis, Sylvia M. Ransford, J. A. Robson, R. C. N. Shires, W. D. Steel, S. A. Underwood, E. M. Wijerama, N. R. W. Wynn-Williams.

* Honours. † Distinguished in Medicine.
‡ Distinguished ... in Surgery.

UNIVERSITY OF DURHAM.

ON June 5th the Duke of Northumberland was installed as Chancellor of the University of Durham, in succession to the late Earl of Durham. The first part of the ceremony was held in the quadrangle of Durham Castle, where the Vice-Chancellor, Sir Thomas Oliver, M.D., conferred upon the Duke the degree of D.C.L. by diploma and installed him in office. After a thanksgiving service in the cathedral, when an address was given by the Bishop of Durham, convocation was resumed in the Chapter House, where the new Chancellor conferred honorary degrees upon a

number of distinguished persons, including the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England, who each received the degree of D.C.L. Sir John Rose Bradford was presented by Professor Stuart McDonald (Dean of the College of Medicine) and Lord Moynihan by Professor Grey Turner. The degree of D.Sc. was conferred on Lord Rayleigh, Emeritus Professor of Physics in the Imperial College of Science, and on Dr. C. Tait Regan, Director of the Natural History Museum.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

[illegible]y, President of the Irish Medical Council, [illegible] College, Dublin, and Vice-Chancellor of the [illegible]y of Ireland, has been unanimously elected an honorary Fellow of the College.

The following candidates, having passed the examination for the Membership, were duly admitted as Licentiates in Medicine and Members of the College: J. Lait and F. MacSorley.

Reports have been received from the representatives of the College on the Irish Medical Council and on the General Medical Council on the recent proceedings of those bodies.

Medical News.

THE William Mackenzie medal for 1928 for original contributions to ophthalmology of outstanding merit has been awarded to Mr. W. S. Duke-Elder of London. The Glasgow Eye Infirmary, the custodians, have made the award on the advice of a committee representative of the University of [illegible] the Glasgow Eye Infirmary and of [illegible] Institution, and the Fellows of the [illegible] Faculty of Physicians and Surgeons of Glasgow.

PROFESSOR GREY TURNER, M.S., F.R.C.S., professor of surgery in the University of Durham, is taking charge of the teaching in the surgical unit of St. Bartholomew's Hospital, in place of Professor Gask, for a fortnight from June 10th to 22nd. It will be remembered that on former occasions Professor Harvey Cushing of Boston, Professor Hugh Cabot of Ann Arbor, and Lord Moynihan have acted in a similar way.

THE third annual MacAlister Lecture of the London Clinical Society will be delivered at the London Temperance Hospital, Hampstead Road, N.W.1, on Thursday, June 20th, at 8.45 p.m., by Sir Humphry Rolleston, on "Medical friendships, clubs, societies." The lecture is open to all medical practitioners, who are invited to bring their friends, ladies or gentlemen. The honorary secretary, Dr. F. Temple Grey, 25, Harley Street, W.1, will be glad to be notified of those who propose to attend.

A COURSE of instruction in the technique of tissue culture will be given at the Strangeways Research Laboratory from July 9th to August 10th. Only a limited number of applicants can be received. Notification from those wishing to take the course should be sent, not later than June 30th, to Dr. H. B. Fell, Strangeways Research Laboratory, Cambridge.

THE summer meeting of the Section of Otology of the Royal Society of Medicine will be held at Cambridge on June 21st and 22nd. A cinematograph demonstration of a prostatectomy, a litholapaxy, and an internal urethrotomy will be given at the summer meeting of the Section of Urology on June 27th, at 8.30 p.m.

A MEETING of the Biochemical Society will be held at the John Innes Horticultural Institution, Merton, Surrey, to-day (Saturday, June 15th), at 11.45 a.m. The subjects on which communications will be made include: carbohydrate metabolism in avitaminous birds, absorption of liquid paraffin from the alimentary tract of the rat and pig, the association of vitamin A activity with carotene in the carrot root, and the nature of the vitamin A constituent of green leaves.

THE annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded will be held at the Sandlebridge Institution, Alderley Edge, on Friday, June 21st. The chair will be taken by Sir Lewis Beard at 3.15 p.m.

THE annual meeting of King Edward's Hospital Fund for London was held at St. James's Palace on June 11th, the Prince of Wales presiding. In the course of his address His Royal Highness read a message from His Majesty the King, expressing delight at the response which had been made to the recent appeal for funds, and stated that during 1928 the amount distributed had for the first time reached a total of £250,000. Loans of radium, bought with Sir Otto Beit's gift, had been made to twenty hospitals, on the principle that there should be a few hospitals with a sufficient supply to act as radium centres, and a rather larger number with enough radium to provide effective treatment. The Prince paid a tribute to the generosity of the British public, which in the course of a single week contributed the money required for the radium side of the Thank-offering Fund. An account of the proceedings of the meeting will be given in next week's issue.

A CROWDED congregation, consisting largely of patients of the late Dr. R. E. Ingram-Johnson, filled the parish church of South Moor, Durham, on June 2nd, when a brass tablet to his memory was unveiled by Sir Thomas Oliver, Vice-Chancellor of the University of Durham. After its dedication by the Rural Dean, Sir Thomas Oliver addressed the congregation, paying a special tribute to the unselfishness that had always characterized Dr. Ingram-Johnson. Sir Thomas spoke in warm terms of the friendship between them, and mentioned the regret he had felt when Dr. Ingram-Johnson decided to go out to India and later to Malaya. There he had devoted himself particularly to the problem of malaria, and had conducted research which led him to the belief that treatment with the serum of dengue fever cases had a definite curative value in malaria. Dr. Ingram-Johnson, who died in May, 1923, was a strong supporter of the British Medical Association.

THE Fellowship of Medicine and Post-Graduate Medical Association has arranged two lectures for candidates for the M.R.C.P. examination, one by Dr. H. Gardiner-Hill on June 18th, and the other by Dr. Harold Pritchard on June 21st, at 8.30 p.m., at 11, Chandos Street, Cavendish Square, W. A free lecture on the management of patients suffering from cancer of the breast will be given on June 18th, at 4.45 p.m., by Dr. Hernaman-Johnson, at the British Institute of Radiology, 32, Welbeck Street, W. There is one week left of the following courses: in ophthalmology, at the Royal Westminster Ophthalmic Hospital, in diseases of the chest, at the Victoria Park Hospital, Victoria Park, E., in gynæcology, at the Chelsea Hospital for Women. From June 24th to 29th an all-day course in proctology will be given at St. Mark's Hospital for Diseases of the Rectum; fee £3 3s. From June 24th to July 6th the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.) has arranged an intensive "refresher" course in medicine, surgery, and the specialties; fee £5 5s. or £3 3s. for either week. Also beginning on June 24th and continuing until July 7th, the Children's Clinic, in association with several other hospitals, will give a comprehensive course of instruction in diseases of children and infants; fee £2 2s. Copies of all syllabuses, the complete list of special courses for 1929, information on general post-graduate work, and specimen copies of the *Post-Graduate Medical Journal*, may be obtained from the secretary, Fellowship of Medicine, 1, Wimpole Street, London, W.1.

WE are informed by Sir James Barr that the following names are to be added to the signatories of the letter published on May 11th (p. 879) in support of the testimonial to Sir Ronald Ross: Professor Umberto Gabbi (Turin), Professor C. Savas (Athens), Dr. Anton Breinl (Townsville), and Professor C. Schilling (Berlin). A list of contributors to the fund was printed in our last issue (p. 1055). Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15, cheques to be crossed "Ross Award Fund a/c."

THE Medical Research Council, after consultation with the Ministry of Health and the Board of Education, has appointed a committee to inquire into the prevalence and mode of spread of minor epidemics in residential schools, especially those believed to be spread by "droplet infection," and to report upon the means by which they may be prevented or restricted. The personnel of the committee is as follows; Sir George Newman, M.D. (chairman), Dame Janet Campbell, M.D., Dr. R. H. Crowley, Surgeon Commander S. F. Dudley, Dr. J. A. Glover, Professor M. Greenwood, F.R.S., Dr. L. R. Lempriere, Miss E. M. Newbold, M.A., and Professor W. W. C. Topley, M.D., with Dr. Joyce Wilson as secretary.

IN continuation of the series of visits to famous buildings in aid of King Edward's Hospital Fund for London, arrangements have been made for parties to visit the Foreign Office, India Office, and Admiralty on Saturday, June 22nd, at 2.45 p.m. On Friday, July 19th, at 4.30 p.m., a party will be conducted round Westminster Abbey, and on August 9th and 21st, at 2.30 p.m., visits will be paid to the Tower of London, when Mr. Walter Bell will give an address on the Tower and its history. Tickets, price 7s. 6d., can be obtained on application to King Edward's Hospital Fund for London, 7 Walbrook, E.C.4.

AT a meeting of the Central Midwives Board for England and Wales held on June 6th, with Sir Francis Champneys in the chair, a letter was read from the town clerk of York, submitting a scheme of lectures to be delivered at York Maternity Hospital by Dr. A. M. Hughes and Dr. Lister. The scheme was approved.

THE Medical Research Council announce that on behalf of the Rockefeller Foundation they have made the following awards of travelling fellowships for the academic year 1929-30: Olive Burton Buckley, B.M., M.R.C.P., King's College Hospital, London; George Aleck Crocker Gough, B.Sc., Ph.D., National Institute for Medical Research,

London; William Robert Henderson, M.B., Royal Infirmary, Edinburgh; Donald Hunter, M.D., F.R.C.P., assistant physician, London Hospital; George Eric Lewis, B.A., M.R.C.S., London Hospital; Moses Myer Suzman, M.D., M.R.C.P., College of Medicine, Newcastle-upon-Tyne; Janet Maria Vaughan, B.A., B.M., University College Hospital, London. These Rockefeller medical fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine and surgery, and who are likely to profit by a period of work at a chosen centre in America or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles. Dr. Gough's fellowship is tenable at the University of Münich; the others at centres in the United States. Dr. Lewis has been appointed on modified conditions while receiving emoluments from another source.

ON June 10th, at the Tower Bridge Police Court, a man charged with obtaining money by false pretences and with intent to defraud, pleaded guilty and was sentenced to imprisonment for three months in the second division. On behalf of the Pharmaceutical Society of Great Britain it was stated that the accused, having represented himself as a fully qualified chemist, obtained the post of manager to a chemist's shop. In substantiation of his claim he had produced a certificate under the Act which, though genuine, had been altered by the substitution of the accused's name for the one it bore originally. The accused, in the course of a statement, said that since he had managed the shop he had dispensed 50,000 prescriptions, and there had never been any trouble and everything had been in order.

THE ninth annual congress known as the Journées Médicales de Bruxelles will be held at Brussels from June 22nd to 26th, under the presidency of Professor Henry Coppez. Addresses will be delivered, among others, by Emile Sergent of Paris, Blum of Strasbourg, Nordenson of Upsala, Spillmann of Nancy, Putti of Bologna, Froment of Lyons, Eastman Sheehan of New York, Gonin of Lausanne, Hymans van den Bergh of Utrecht, and Tricot-Royer of Antwerp. The opening discourse will be given by the Parisian oto-rhino-laryngologist, Dr. Nepveu, who is well known in the literary world, as Luc Durtain. The subscription is 75 francs. Further information can be obtained from the general secretary, Dr. R. Beckers, 62, Rue Froissart, Brussels.

DR. G. WAYLAND ANCRUM of Gloucester and Dr. Richard Davies of Cheltenham have been appointed to the Commission of the Peace for the county of Gloucester.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

UMBILICAL DISCHARGE.

"W. D." writes: Can anyone suggest the cause of an occasional discharge from the umbilicus in a woman of 32? The discharge is serous in character, and occurred first at about the age of 14 years, and reappeared about three years ago.

WATER SOFTENERS.

"MEMBER OF FORTY YEARS' STANDING" asks whether it is advisable to use for the whole of the water supply (Kentish hard water) to his house one of the water softeners on the market. Is the softened water palatable, and does it contain any substance injurious to health? Is any one method of softening specially recommended?

INCOME TAX.

Appointment: Whether Liable to Tax.

"W. H. P." first commenced earning a salary in September, 1926, as an assistant, and his earnings have been as follows:

September, 1926, to December, 1926	£69
Year to December, 1927	£231
Year to December, 1928	£290
Three months to April, 1929	£109

He inquires whether he is liable to assessment, and as to what steps he should take.

*** He is liable as follows:

For the year 1926-27: £69+one-quarter of £231—that is, £127—exempt.
For the year 1927-28: three-quarters of £231+one-quarter of £290—that is, £245—£6 18s. tax.
For the year 1928-29: three-quarters of £231+one-quarter of £290—that is, £245—£6 18s. tax.

In explanation of the above the basis of assessment was the current year's earnings up to 1927-28 inclusive, and afterwards the previous year's earnings; in calculating the tax payable only earned income relief and the £135 personal allowance have been deducted; any life assurance relief would reduce the tax payable still further. It will probably be best for "W. H. P." to get in touch with the local inspector of taxes and make his formal returns.

Change of Employment.

"R. C. F. S." was acting as a general assistant to December 20th, 1927, and became a school medical officer under a public authority as from January 1st, 1928. What is his correct basis of assessment for the year to April 5th, 1928?

*** The actual amount of his earnings for that year. Where a substantial change in the nature and conditions of the employment takes place, as has occurred here, the correct method is to regard the former employment as having ceased and a new one as having commenced. The facts do not justify a claim to continuity of employment.

LETTERS, NOTES, ETC.

THE COCKTAIL HABIT IN FRANCE.

IN our issue of January 5th (p. 31) we noted Professor W. E. Dixon's warning about the injurious effects of cocktail addiction; recently a similar denunciation has been made at the Académie de Médecine by Professor Georges Guillain, who occupies the chair of nervous diseases in the Paris Faculty of Medicine. Before the war, he states, this practice, imported from America, had been confined to certain sections of French society, particularly racing, literary, and dramatic circles, but lately it has become prevalent among the well-to-do classes generally. The cocktail bar is to be found not only in hotels and restaurants, but even in the homes of the rich. Furnishing firms make it their business to supply more or less elegant bars suitable for drawing rooms, even for motor cars, while special hampers containing the ingredients and utensils used in the preparation of cocktails are on sale everywhere. As in this country, the principal victims of the habit are young men and women of the "smart" set, and among them Professor Guillain has often found obvious signs of chronic alcoholism. Commonly met with are digestive disturbances, manifested as loss of appetite, hyperchlorhydria, pyloric spasm, congestion of the liver, and enteritis, and such circulatory symptoms as tachycardia, precordial pain, and a tendency to syncope. The most important disorders, however, are referable to the nervous system, and include insomnia, physical and psychical asthenia, depression, and disinclination for mental work. In several instances epileptic attacks, attributed to the cocktail habit, have occurred for the first time in individuals of 25 to 35 years of age. Professor Guillain urges that young people of the wealthy classes should be enlightened as to the disastrous effects of cocktail drinking, both on their own physical and mental equilibrium and on that of their descendants.

VOTES FOR EPSOM COLLEGE.

DR. BERNARD ROWLANDS (London, N.15) writes: I appeal on behalf of John Horace Brockman White to any who have votes for Epsom College. Contemporaries of his father, Charles Powell White, M.A., M.D.Camb., F.R.C.S.Eng., who knew him as a good surgeon and research worker, will regret to know that this appeal is necessary.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 47, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44, 45 and 46.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 235.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

568. Ulcerative Colitis.

J. A. BARGEN and M. F. JACOBS (*Arch. Int. Med.*, April, 1929, p. 483) assert that *perforations of the colon* constitute one of the most serious complications in chronic ulcerative colitis, although they are frequently not recognized owing to the extreme illness of the patient masking the symptoms. Of 647 cases of the disease at the Mayo Clinic during five and a half years, perforations occurred in 22 (3.4 per cent.); 16 patients died, the mortality rate being 72.7 per cent. The majority of the patients were between the ages of 35 and 50, and the duration of the disease, which ranged from two months to thirty-five years, appeared to have but little bearing upon the incidence of perforation. The extent of bowel involvement was found to be more significant, the entire large bowel being diseased in 17 of the 22 cases. Notes of four of the cases are given. The authors remark that this disease presents a typical proctoscopic picture, the mucosa bleeding easily and presenting multiple irregular ulcers, with some bowel contraction. Perforation may be acute, chronic, or multiple, and abdominal pain, cramps, tenderness, and rigidity are the commonest among the symptoms. Recognition of the disease in its early stages before involvement of the entire colon has taken place is essential to successful treatment; a routine proctoscopic examination is advised in all cases of diarrhoea and bleeding from the rectum. When perforation has occurred treatment is mainly expectant, since an operation gives but little promise of cure. Ice bags or hot fomentations are applied to the abdomen, and no food or fluid is given by the mouth; sodium chloride solution is injected subcutaneously, and dextrose and sodium chloride solution intravenously. In addition to these measures opiates and blood transfusion constitute the main lines of treatment.

569. Essential Arterial Hypertension.

M. MOLHANT (*Le Scalpel*, March 23rd, 1929, p. 309) classifies cases of "essential" hypertension (distinguished from those secondary to renal lesions) according to the exciting causes of the condition, and outlines the appropriate treatments. He considers that the "dynamic constant" of arterial tension, as measured by the sphygmomanometer, may be taken in the healthy adult to be from 110/65 to 130/80. The maximum depends on the elasticity or tone of the arterial walls, and the minimum on the arterio-capillary tone, which in turn has an important relation to the state of the great venous reservoirs, particularly those of the abdomen. This tone is regulated by a double mechanism: the well-recognized psychic factors and the biological mechanism, which according to Molhant may be either automatic (in response to some form of shock, including that due to anaphylactic phenomena) or reflex. Molhant considers that the action of internal secretions on the arterial tension is not in every case dependent on nervous control; although the action of some visceral secretions is not yet fully understood, there appears to be a double and antagonistic system acting on the arterial tone. Hypotonic glands are the liver, genital glands, pancreas, lymphatic glands, and suprarenal cortex. The hypertonic glands are the thyroid gland, the suprarenal medulla, and the posterior part of the hypophysis. As distinct from cases where increased tension is the physiological response to unhealthy habits, when treatment by dieting is the obvious remedy, Molhant recognizes a large class where there exists a nervous dyscrasia susceptible to treatment by "hyperallergization" or by the exhibition of colloidal iodine, the action of which he regards as that of a catalyst acting on the hypotensive internal secretory glands. He further recognizes two groups of cases with increased tension according to the sphygmomanometric readings: (1) those with a "divergent" reading—200/95 to 170/85; and (2) those with a "*convergent*" reading—200/135 to 195/120. He considers that all the forms of hypertension are intimately connected with dyscrasic processes; in its dynamic form it depends on an allergic insufficiency of the tissues and fluids, giving rise to derangement of the reflex regulatory mechanism, whereas in its static or permanent form it is due to catalytic hypotension or inexcitability of the hypotensive endocrine system. The treatment is tabulated according to the pathogeny and clinical symptomatology as follows. (1) In "*dynamic hypertension*" due to allergic insufficiency "hyperallergization" by subcutaneous injections is employed. (2) In permanent hypertension of the "divergent" type due to catalytic deficiency of the hypotensive endocrine system, colloidal iodine and concentrated vitamins are indicated. (3) Permanent hypertension of the "convergent" type signifying arterio-capillary fibrosis and, if partly reducible, due to catalytic hypo-excitability of the hypotensive endocrine system, calls for repeated courses of colloidal iodine and occasional drastic purgation. (4) Permanent hypertension of the "convergent" type, if irreducible and due to catalytic inexcitability of the above system, is treated by the regular repetition of drastic purgation.

570. Maternal and Congenital Syphilis.

A. BUSCHKE (*Med. Welt*, April 20th, 1929, p. 566), in discussing the generally accepted theories regarding the transmission of syphilis, states that recent researches have proved that there are exceptions to the "Colles-Beaumès law." Spirochaetes have been demonstrated in the maternal placenta, and not infrequently these patients have developed tertiary syphilis and tabes subsequently. It is essential, therefore, that all mothers of syphilitic children should be carefully examined for latent syphilis. A theory has been advanced recently that the child may be infected at birth by laceration of the placental tissue and consequent liberation of spirochaetes therefrom. This would explain the fact that some children appear to be healthy at birth and develop symptoms of syphilis only three or four months afterwards. Buschke refers to the divergent views of various writers on the subject of the antisyphilitic treatment of expectant mothers. Some advise intensive salvarsan treatment; others mercury and bismuth or a mixed treatment. He prefers this combined treatment in the earlier stages. Doubtless intensive salvarsan treatment, followed by combined treatment, gives excellent results in regard to the child, but, on the other hand, salvarsan treatment is not free from danger for the mother, in two directions. Several fatal cases of encephalitis have been recorded after administration of small doses of neosalvarsan. If salvarsan is administered to the mother in small doses the dangers of such manifestations as neurosyphilis and syphilitic aortitis are greatly increased, although, on the other hand, salvarsan treatment offers the probability, but not the certainty, of a healthy child. There is also the danger of nephritis to be considered when salvarsan is administered during pregnancy. Buschke prefers mercurial inunction or bismuth injections, commenced as early as the fourth or fifth month, and adds that the treatment should be given in monthly courses with intervals of eight to fourteen days between each course. When possible it should be continued until the end of pregnancy, the dosage and length of treatment being modified when the patient's condition requires it. Statistics show that this method of treatment gives results as favourable as those obtained from salvarsan. Records collected during the period before the introduction of salvarsan prove that under mercurial treatment alone 88 per cent. of apparently healthy children were born, and that with less intensive and later treatment than is now advocated. Buschke considers, therefore, that mercurial or combined treatment yields most favourable results with greatly diminished risk as regards the mother.

Surgery.

571. Thrombo-angiitis Obliterans.

A. M. BECHTMAN (*Med. Journ. and Rec.*, April 3rd, 1929, p. 367) discusses the etiology, pathology, symptoms, diagnosis, and treatment of thrombo-angiitis obliterans (Buerger's disease), and endeavours to correlate the subject from an experience of excellent results in his own practice. The pathological process includes an inflammatory condition of the arteries and veins, with the presence of giant cells and cellular thrombosis in the acute lesions; periarterial fibrosis follows in the chronic stage. The disease appears in adult males between the ages of 20 and 50; they are usually large users of tobacco and, in 50 per cent. of the cases, of Hebrew extraction. It presents the characteristic colour changes in the extremities of rubor on depression and pallor on elevation, differentiating the functional from the organic conditions. The pedal pulse is absent, intermittent claudication is frequent, and in about one-third of the cases the parts are cold and superficial phlebitis is present. In the prevention of gangrene early diagnosis and the institution of prophylactic and active treatment are important, with the avoidance of meddlesome surgery of the toes and nails, which may lead to trophic changes. Protection of the extremities from cold and injury,

and the wearing of suitable shoes, are essential; an occupation should be chosen which does not entail weight bearing on the feet over long periods. Patients are of three types: (1) those in whom gangrene has progressed so far that amputation is imperative; (2) those in whom gangrene results in spite of all treatment; and (3) those whose limbs can be saved and the disease arrested by long and efficient treatment, rendering them eventually self-supporting and useful citizens.

572. Thrombo-angiitis Obliterans involving Spermatic Vessels.

A. L. MCGREGOR and F. W. SIMPSON (*Brit. Journ. of Surg.*, April, 1929, p. 539) report a case of thrombo-angiitis which affected the spermatic vessels. Buerger, whose name has been given to the disease, describes it as an occlusive thrombotic process involving the deep arteries and veins or superficial veins of the upper and lower extremities, manifesting itself as an inflammatory lesion which shows a specific and characteristic morphological picture during the process of healing. In the early or acute stage the appearance of purulent foci suggest a microbial agent or infectious causative factor. Out of 500 patients, 496 were Jews, commonly in the third decade of life, and only 3 were women. It is suggested that tobacco smoking brings about changes in the walls of the vessels and renders them liable to attacks of inflammation and thrombosis. Although the lower limbs are the most common seat of the disease, cases have been reported in the spermatic artery, in a branch of the gastric artery, and in the spermatic vessels of the cord. The first stage is often an acute phlebitis of the superficial veins, with swelling of the feet and tender inflammatory nodules in and under the skin, followed by pain and intermittent claudication. Pronounced vasomotor and trophic disturbances occur, with erythromelia, ischaemia, cyanosis, ulcers, and gangrene. The case reported occurred in a Russian Jew, aged 28, who complained of pain and irritation over the left half of the scrotum and over the penis and lower abdominal wall; it recurred daily for two or three hours. The left testis was smaller than the right; the epididymis contained two nodules in the caput and one in the cauda. After two months the symptoms were accentuated, and an operation on a diagnosis of tuberculous epididymitis was performed. The testis was removed with the cord as far as the internal ring, and the wound healed by first intention. On dissection the vas deferens was found to be normal, the apparent thickening of its upper part being due to the firm adhesion of many blood vessels to the periphery of the vas, giving the impression on palpation that this tube was much thickened. Histological changes found in the spermatic vessels were those of thrombo-angiitis obliterans. The disease is characterized by relapses, and the patient has had pains since operation in the remaining testis, suggesting the possibility that it also may become affected. The prognosis for life is good if the disease is localized in the scrotum. In cases where the limbs are affected amputation is the only sure treatment; though other methods of treatment relieve the symptoms temporarily, the gangrene ultimately occurs, and amputation becomes inevitable.

573. Dupuytren's Contracture.

A. OLLER (*Arch. de med., cir. y esp.*, March 16th, 1929, p. 333), who records an illustrative case, maintains that Dupuytren's contracture is not to be considered as an industrial accident. His reasons are as follows. Among the millions of workmen who suffer from haematomas and repeated traumas on their hands Dupuytren's contraction develops in only a very small number. A larger proportion of cases of Dupuytren's contraction are to be found in liberal professions than among manual labourers. The contraction is nearly always bilateral, whereas in almost all work only one hand is actively employed. When the contraction is confined to one side, it is almost always situated in the hand which does the least work. Oller recalls that at the fourth congress on industrial accidents, held at Amsterdam in 1925, the view was expressed that Dupuytren's contraction was not an industrial accident; he mentions that the textbooks of Leniger, Molineus, and Jottkowitz, published in 1928, are of the same opinion.

574. Ectopia of the Spleen.

E. PERINI (*Rass. internaz. di clin. e ter.* (Naples), March 30th, 1929, p. 198) records the case of an ostler, aged 40, who was admitted to hospital with severe abdominal pain and ineffectual attempts to vomit. He gave a history of having been kicked by a horse in the upper left quadrant of the abdomen four years previously, and of having had the tenth and eleventh ribs fractured also by a horse's kick two years later. Since then he had remained in good health until his present illness. During his stay in hospital he had a considerable amount of melaena without anything to account for it. The urine was normal and the Wassermann reaction negative. The abdominal pain, which was at first generalized, suddenly assumed the character of renal colic, but cystoscopy and examination of the right ureter revealed nothing. It was found impossible to pass even a small catheter into the left ureter. *X* rays showed a large shadow in the left hypochondrium, suggesting hydronephrosis caused by a calculus. The pain gradually subsided and laparotomy was not performed until the following year, when a spleen of practically normal size was found with torsion of its pedicle, its upper pole adherent to the diaphragm and the lower pole perpendicular to the costal arch and pointing downwards and backwards. Splenectomy was performed and recovery followed. The melaena during the first stage of the disease was explained by obstruction to the splenic circulation, which caused engorgement and rupture of the mesenteric vessels.

Therapeutics.

575. Antitoxin Treatment of Diphtheria.

V. BIE (*Deut. med. Woch.*, April 5th, 1929, p. 563) reports on the treatment, by large doses of serum, of 1,113 cases of diphtheria occurring in the Blegdamm Hospital in Copenhagen during five months—September 1st, 1928, to January 31st, 1929. The cases were considered in three groups. In 687 slight cases, including those in which the false membrane did not extend beyond the tonsils and there was only exceptionally catarrh with periadenitis, the patients received 16,000 units; there were no deaths. In 315 cases of medium severity, including those in which the membrane covered the tonsils and extended to the margin of the uvula, being associated with catarrh, fetor, more or less periadenitis, and occasionally albuminuria, the patients received 32,000 to 48,000 units, which was sometimes repeated on the following day; of these, three died (0.96 per cent.). There were 111 severe cases; in these the membrane reached to the uvula and more or less covered the soft palate, sometimes involving the hard palate and mucous membrane of the cheek and posterior wall of the pharynx, and being usually accompanied by catarrh, fetor, albuminuria, and severe periadenitis. These patients received 80,000 to 100,000 units, which might be increased by 50 to 100 per cent. Of these patients, 20 died, 5 within twenty-four hours; if these are excluded, the mortality is only 14.15 per cent., and the total mortality is 1.62 per cent. The serum for the intramuscular injections contained 700 antitoxin units per cubic millimetre; for intravenous injections 800 to 1,600 units; for intravenous administration the maximum dose was 50 c.cm. for adults and 1 c.cm. per kilo body weight for children.

576. Copper Treatment in Syphilis.

J. VIGNATI (*Derm. Woch.*, May 4th, 1929, p. 644), inspired by the work of Dajiro and Anjow on the spirillicidal action of copper, decided to make use of it in the treatment of syphilis. He employed a combination of copper and sodium thiosulphate (Cu-Devenau) and investigated its spirillicidal action, its influence on the Wassermann reaction, human tolerance, and the effects of the treatment, with the following results. The spirillicidal action of copper was found to be considerable; complete or partial disappearance of the spirochaetes from the syphilitic eruption ensued, and the clearing up of the rash and gummata was obvious. The effect on the Wassermann reaction was, however, very slight. The preparation was well tolerated by all patients, and no albuminuria or any other sequels were observed. The absence of any bad effects was attributable to the combination of copper with sodium thiosulphate.

577. Treatment of Rickets with Irradiated Ergosterol.

E. T. WILKES, D. W. FOLLETT, and ELEANOR MARPLES (*Amer. Journ. Dis. Child.*, March, 1929, p. 483) exhibited a commercial preparation of irradiated ergosterol successfully employed in twenty-four infants with mild to severe rickets. This preparation, given in doses of 3 mg. a day, required about three weeks to cause the serum phosphorus content and the calcium concentration to return to normal—about the same time for *x*-ray signs of healing of the bones to appear—and about six weeks for complete cure. These averages compare favourably with those obtained with cod-liver oil, quartz light, and egg. Craniotabes was healed within an average of one month in their series of twelve cases. In prophylaxis their experience was limited to eight cases, in which 3 mg. a day was given, beginning at the age of 2 weeks. One premature infant developed craniotabes when 3 months old, despite the ergosterol, but the condition disappeared with a further four weeks of the same treatment. Two patients in the series had tetany, which was cured

within eight days with the ergosterol, no other treatment having been given. The authors note, however, that caution may be necessary in using irradiated ergosterol in patients with tetany who show a high blood phosphorus content.

578. Treatment of Tuberculous Glands by Sodium Cacodylate.

J. L. Y GAÑÁN (*Arch. de med., cir. y esp.*, March 30th, 1929, p. 411) records his clinical and histological observations on two cases of tuberculous adenitis treated by intravenous injections of 20 per cent. solution of sodium cacodylate. The dose was at first 1 c.cm., and then gradually increased by ½ c.cm. to 7 c.cm., which was equivalent to 1 gram 40 *cg.* of the drug. The author comes to the following conclusions. Sodium cacodylate in progressive doses is one of the most efficacious remedies we possess for the treatment of chronic tuberculous adenitis. It has a beneficial action on the lympho-granulomatosis, which, though probably of tuberculous origin, has not been definitely proved to be so. It does not give rise to any disagreeable symptoms if the tolerance of the patient is carefully watched. Its mode of action is very similar to that of *x* rays without having any of the disadvantages of the latter. Sclerosis takes place through vascular changes in the gland.

579. Mercurochrome in Septicaemia.

S. H. ZIA, R. H. P. SIA, and S. T. WOO (*Nat. Med. Journ. of China*, April, 1923, p. 117) review the literature relating to the value of the intravenous administration of mercurochrome-220 in the treatment of septicaemia. They report a comparative study of ninety-four septicaemic cases, some of which were treated in this way, and some by other forms of intravenous therapy. They conclude that the mercurochrome treatment has no particular value in this connexion and that it may possibly do harm. Clinical symptoms of mercurial poisoning were often encountered, but were not very alarming. The authors report some experimental studies in this connexion; they found that mercurochrome did not seem to exert any beneficial action on the course or final outcome of septicaemia produced artificially in rabbits.

Ophthalmology.

580. Detachment of the Retina.

M. D. ANKLESARIA (*Indian Med. Gaz.*, April, 1929, p. 186) believes that detachment of the retina should be regarded as a sign rather than a disease, and suggests that it may be caused by a number of essentially different lesions. From a developmental viewpoint, a weak spot exists in the interretineal space between the pigment epithelium and the other layers of the retina, including the rods and cones. When a separation occurs it does so at this point, the pigment epithelium still remaining adherent to the choroid, and the intervening space being filled by serous fluid. A detachment usually originates in one of three ways. The retina may be pushed in or pressed away from the choroid into the vitreous chamber by a force greater than the vitreous tension; it may be pulled into the vitreous chamber owing to skrinkage of the vitreous; or the condition may be due to a hole or holes in the retina, the retina being floated in by the passage of fluid vitreous through an aperture in it. Detachments of the retina may be divided into two main groups: the simple, primary idiopathic or non-traumatic; and the secondary or symptomatic. The pathogenesis of the former, the majority of which are myopic detachments, is very obscure, and the prognosis is bad, as the prospects of cure even after long and tedious treatment are problematical. The most generally accepted views as to the genesis of this form of retinal datachment are: the exudation theory, subsequently modified by Raehlmann and called the diffusion theory, and the vitreous traction theory of Leber and Nordenson. Both these theories are fully discussed. Anklesaria reports a case in a student, cure being obtained by medical measures combined with rest in bed. Complete physical and physiological rest was enjoined. Both eyes were bandaged, and injections of saline solution, commencing with 4 per cent. strength and increasing to 10 per cent., were given in Tenon's capsule over the site of the detachment. Internally, the patient was given 7 grains of urotropine twice daily, on account of its supposed salutary action on the secretions of the ciliary body, and a mixture containing potassium iodide and sodium salicylate with salines. In six weeks much improvement was noted. A severe attack of typhoid fever, which lasted six weeks, then supervened, from which the patient eventually recovered. An ophthalmoscopic examination eleven months after the detachment revealed no evidence of its existence; the retina was found completely re-attached and fully functioning, and the patient has resumed his studies.

581. Medical Treatment of Glaucoma.

CH. ABADIE (*Presse Méd.*, February 16th, 1929, p. 220) defines three types of glaucoma: the acute, subacute, and simple chronic. The acute form, easily diagnosed, is marked by a sudden onset with violent orbito-frontal pains. The globe is injected, and is hard and resistant on palpation; the cornea loses its transparency and becomes blurred and greyish-white, permitting, however, the dilated pupil to be visible. Vision is completely lost. In the subacute form, characterized by intermittent crises, the patient sometimes notes coloured circles resembling a rainbow; this is a pathognomonic sign of a glaucomatous crisis. Sometimes more or less complete blindness lasts for an hour or two. In the intervals between attacks the optic conditions are normal. The attacks become more frequent, and finally the hypertension persists and blindness supervenes. In simple chronic glaucoma the vision progressively and very slowly decreases, the visual field gradually retracting, especially on the nasal side. Diagnosis is difficult, as certain atrophies of the optic nerves show almost the same evolution; it can only be made by ophthalmoscopic examination, glaucomatous atrophy presenting the characteristic excavation. Abadie does not agree with those who hold that glaucoma is due to an obstacle to the filtration of the intraocular fluids at the irido-sclero-corneal angle, but maintains that it is a result of an abnormal dilatation of the vessels of the eye innervated by the ocular sympathetic. In support of this view he states that administration of certain vaso-constrictor drugs causes its disappearance, and he is a strong advocate of medical rather than surgical treatment. The method recommended is to give daily two spoonfuls of the following mixture a quarter of an hour before food: fluid ergot 2 grams, calcium chloride 20 grams, water 200 grams. In addition he advises that two or three drops of the following solution should be instilled into the eyes thrice daily: pilocarpine nitrate 0.2 gram, distilled water 10 grams. Abadie reports great benefits from this treatment, and cites four cases in which the patients suffered from glaucoma in both eyes. Those patients in whom the eyes were treated medically recovered, while in those submitted to operation the vision was lost. The author adds that this treatment does not preclude subsequent operation, and, in fact, renders the eye more suitable for surgical intervention.

582. Uveal Cysts of the Iris.

REVIEWING the cases of uveal cyst of the iris recorded in the literature, W. H. WILMER (*Arch. of Ophthalmol.*, February, 1929; p. 162) remarks that with more exact methods of examination these cysts are found not to be so rare as was formerly thought. A further case is reported in which both eyes showed total posterior synechiae with iris bombé, and from the posterior pupillary margin of the left one a dark brown, non-translucent, granular mass was seen to protrude. Transfixion of the iris was performed on the left eye, and three weeks later the sclero-cornea was trephined with peripheral iridectomy. With the reduced tension the cyst collapsed, and later the opaque lens was removed. Cysts of the iris have been classified, according to their position, into cysts of the anterior layers of the iris, those free in the anterior chamber, and those of the pigment epithelial layer. The latter can be further subdivided into the primary, and those following synechiae with glaucoma. The exact genesis of these cysts is not yet definitely fixed. Of 36 reported cases, 20 were primary, 7 were caused by injury, 3 were consequent on glaucoma after injury, and 6 followed occlusion of the pupil or glaucoma. Spontaneous cysts are interesting both from their pathogenesis and also from the fact that, although they are true cysts, in some cases their walls are so translucent and seemingly so solid that the possibility of malignancy must be considered. In 6 cases the affected eye was removed owing to an erroneous diagnosis of melano-sarcoma; such growths are found in a position similar to that of spontaneous cysts. In some cases of primary cysts of the iris a true diagnosis can only be made by the removal of a piece of the iris with the cyst. When the eye is painless and there is useful vision this or some similar procedure should be resorted to before enucleation.

583. Naevus of Bulbar Conjunctiva.

F. H. RODIN and E. M. HALL (*Amer. Journ. Ophthalmol.*, January, 1929, p. 24) describe a case of pigmented naevus of the bulbar conjunctiva occurring in a boy aged 6. It had been first noticed a year previously, and had grown considerably during the year. The naevus was removed by operation, and a year later no recurrence had been detected. Pathological examination of the removed tissue showed pigmented cells of connective tissue arranged in small groups immediately below the epithelium; these cells were of the stellate type (chromatophores). These pigmented naevi of the bulbar conjunctiva are very liable to become malignant in early middle age, and they should be removed.

Obstetrics and Gynaecology.

584. Prevention of Eclampsia.

ACCORDING to G. BAUMGART (*Zentralbl. f. Gynäk.*, March 16th, 1929, p. 647) further diminution of the mortality from eclampsia is more likely to result from earlier recognition of the pre-eclamptic state than from improved treatment of the established disease. Although the three main pre-eclamptic symptoms—albuminuria, oedema, and increase of blood pressure—were recognized as clinical features of eclampsia respectively 89, 135, and 60 years ago, it is only comparatively recently that adequate attention has been given to their importance as precursors of eclampsia. To avoid the occurrence of this condition it is necessary to watch the pregnant patient, and, if the prodromal symptoms are found, to institute, according to Rissmann, Volhard, and others, a starvation regime for some days. Baumgart recommends monthly examinations of the patient, recording of the blood pressure, and investigation of the urine for albumin and casts; instructions are given to the patient to report at once the onset of swelling of the arms, legs, or eyelids. In the seventh month examinations are made fortnightly, in the eighth month weekly, and in the last month twice a week. Oedema, in the absence of albuminuria or cylindruria, usually disappears if the legs are kept high during the night and the patient rests more during the day. If, however, albuminuria is noted (usually in combination with hyperpiesis) the patient is generally—and, if casts are present, invariably—admitted to hospital. There she is kept in bed and nothing is given by the mouth for three days, except (in refractory patients) one or two apples or a banana daily. On the fourth day 9 ounces and on the fifth day 18 ounces of barley water are given, and thereafter return is gradually made to full diet, permanent reduction being maintained, however, in the intake of water and salt. Baumgart reports that of 152 women admitted to hospital with pre-eclamptic signs 22 only had an eclamptic convulsion, but these were all admitted during labour. Records are given of the speedy disappearance of oedema, albuminuria, and urinary casts after the carrying out of this "hunger and thirst treatment" as the sole therapeusis in 15 patients.

585. J. L. MILLS (*Minnesota Med.*, April, 1929, p. 186) believes that the most common finding in the late toxaemias of pregnancy is hypertension, which he classifies as: (1) a benign type—the so-called "nephroses" of pregnancy—occurring early with little evidence of intoxication; (2) a late type, rapid in onset, and in some cases passing into eclampsia; and (3) the hypertension which exists in pregnancy as a result of previous heart or kidney disease. Mills mentions a series of 222 cases of eclampsia reviewed by F. W. Rice; in only 7 per cent. was there adequate ante-natal care. In his own experience 50 per cent. of his obstetrical patients do not seek medical advice until the last month of pregnancy, and accordingly he urges medical practitioners to stress the benefit to be gained by careful supervision during the period of gestation. The treatment of cases of hypertension varies according to the degree of severity of the patient's symptoms. When the blood pressure has risen only slightly, and where the presence of albumin in the urine is doubtful, Epsom salts and a restriction of protein diet are usually enough. If there is not a prompt response to this treatment, confining the patient to bed and allowing milk only are successful in nearly every instance. Where a marked toxaemia with definite pre-eclamptic symptoms is present the author advises conservative treatment, and makes special mention of magnesium sulphate given either intravenously or intramuscularly. If the intravenous route is used, 20 c.cm. of a 10 per cent. solution are given; when injecting the sulphate intramuscularly, 15 c.cm. of a 25 per cent. solution are administered. Ammonium chloride is said to be very useful as a diuretic; to avoid gastric irritation Mills gives it in capsule form. He compares the results obtained by J. W. Williams by (1) operative and (2) conservative methods in dealing with eclampsia. By conservative treatment Williams has lowered his mortality from 24.8 to 13 per cent.

586. Cervico-vaginal Varix simulating Placenta Praevia.

H. NAUJOKS (*Zentralbl. f. Gynäk.*, March 9th, 1929, p. 605) records a case in which severe ante-partum haemorrhage three weeks before term was thought to be of rectal origin; after a vaginal examination it was attributed to placenta praevia. Abdominal Caesarean section was performed at once, but the placenta was found to have a normal high insertion. At the operation large varices were noticed on the anterior wall of the corpus uteri, and, after the operation, on the posterior vaginal wall; during the operation bleeding from the lower end of the uterine incision was persistent and profuse. The ante-partum haemorrhage, it was concluded, had come from varices of the cervical canal and lower uterine segments. Naujoks remarks that present-day teaching in Germany, where in the maternal interest Caesarean section is regarded as the treatment of choice in non-infected cases of placenta praevia, enjoins abstention from vaginal examination—a course which necessarily leads to a small proportion of errors in diagnosis, as in the present case. Caesarean section, however, was the correct treatment of the acute and severe bleeding in this case, and vaginal hysterotomy in the varicose area would have been extremely dangerous. Most commonly cervico-vaginal varix is not associated with varix of the vulva or legs, and occurs in young, healthy primiparae; the bleeding is very profuse, and in more than one-half of reported cases death has followed. In a case described by Wieloch fatal bleeding occurred after delivery of the head in a labour which until then had been normal and bloodless.

Pathology.

587. The Capillary Circulation in Children.

EMPLOYING the capillary microscope in children L. DOXIADES (*Deut. med. Woch.*, March 15th, 1929, p. 438) found that the form of the capillaries depended on the extent to which the lumen of the capillaries was filled; this in turn depended on the tone of the cells constituting the wall of the capillary. Changes in the form of the capillary wall are associated with alterations in permeability of the capillary endothelia. Doxiades examined the capillaries in the nail fold and mucous membrane of the lips in a number of infants and young children suffering from exudative conditions of the skin and found that both the arterial and venous limbs of the capillary loop had comparatively narrow lumina, and that the blood flow in them was accelerated. The exudative diathesis is said to be associated with a congenital increase in the permeability of the capillary wall, and, in comparison with the normal, the susceptibility of the cells constituting the capillary wall to products of metabolism circulating in the blood is also increased. Working in conjunction with Pototzky, he found that when the oral administration of thyroxin to myxoedematous children had been continued for some months the dilated capillaries with sluggish blood flow originally present became transformed into narrow capillaries with an accelerated flow. Examination of 26 rachitic infants who were receiving ultra-violet light treatment revealed an acceleration in the capillary circulation, an increase in the number of capillary loops visible, and a more intensive pink coloration of the corium in 18 cases after the tenth treatment, which involved a twenty-two minutes' exposure; in the remaining 8 infants a similar reaction appeared after ten minutes' exposure. Subsequent examination of the irradiated infants showed that as the cutaneous pigmentation disappeared after the conclusion of the course of treatment the capillary reaction just described also generally subsided. Capillary microscopic examination of a positive cutaneous Pirquet reaction showed a marked increase and dilatation of the capillaries of the skin and oedema of the cells of the corium.

588. Haemolytic Streptococci and Scarlet Fever.

G. MORIWAKI (*Journ. Preventive Med.*, January, 1929, p. 1) found that when there was a case of scarlet fever in a household there were often carriers of haemolytic streptococci among the other members of the family, or that carriers often had sore throats and fever before the onset of subsequent typical scarlet fever. Persons whose throats were found to be free from streptococci on preliminary examination yielded abundant streptococci when they developed scarlet fever. Convalescents might be the cause of return cases if they had relatively abundant haemolytic streptococci when discharged, whereas convalescents free from streptococci never gave rise to return cases.

589. Action of X rays on the Prostate.

P. DEL BUONO (*Riv. di radiol. e fisica med.*, January, 1929, p. 63), as the result of irradiating the prostate of dogs of various ages, comes to the following conclusions. Application of x rays to the prostate of adult dogs produces after a certain time functional and structural alterations which are remarkable for their varied intensity and importance. The diversity of the results appears to depend on other reasons besides the irradiation. The more or less rapid appearance of morbid changes does not seem to be due entirely to the intensity of the irradiations, but depends to some extent on the age of the animal. Though irradiation of the prostate in adult dogs is not followed by death, as in young animals, it nevertheless produces important changes in the organism—namely, increase in weight; areas of alopecia which are at first discrete and then confluent, and are associated with alterations in the colour, lucidity, and elasticity of the skin; and, finally, signs of premature senility.

ELIMINATION of URIC ACID

in Rheumatism, Lumbago, Sciatica, Neuritis, etc., by

AGOTAN

(HOWARDS)

Selected from numerous Clinical reports, the following is of interest to the Medical Profession as illustrating the value of AGOTAN:

M.B., B.Sc., D.P.H.:

Reports that he has achieved success with Agotan when salicylates, iodides, ionisation and diathermy, etc., have all been, to use his own expression, "utterly futile." "With Agotan," he writes, "one can safely prophesy an ultimate cure. Even in cases where ultimate resort had had to be made to morphine this can be discontinued in a very short time. Progress towards recovery is never interrupted by exacerbations as is so common with the majority of other drugs."

AGOTAN (Howards) is available in 7½ grain tablets in 25's and 50's, in 1-oz. bottles of powder, and in tubes for local application.

Samples will be sent to any Doctor on request.

THE HOLBORN SURGICAL INSTRUMENT CO., LTD., 26, THAVIES INN, HOLBORN CIRCUS, E.C.1

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely-deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56. Northampton), who can be seen in London by appointment.

NEURASTHENIA
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1930.

The Senate announce the following vacant External Examinerships for all Examinations above Matriculation for the year 1930. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included.

The Examiners for the Final Examinations will be invited as occasion arises to take part in the Higher Examinations, but the Senate have resolved that in certain cases in which the work is heavy they shall not be required to do so.

For the First Examination for Medical Degrees.
Biology. Chemistry. Physics.

For the Second Examination for Medical Degrees.
Anatomy (two). Pharmacology. Physiology.

NOTE.—One of the two Examiners appointed in Anatomy will be required to act for Science Examinations also.

For Final and Higher Examinations for Medical Degrees.
Medicine. Surgery (two). State Medicine.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable on or before Monday, July 7th, 1929. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

LOCUM TENENS required during July and August for Bacteriological and Pathological work. Salary £12 12s. per week.

Applications should be sent to the Medical Officer of Health, Town Hall, Bradford, as soon as possible.

Town Hall, Bradford. June 7th, 1929. N. L. FLEMING, Town Clerk.

Prison Medical Service.

Applications are invited for the post of MEDICAL OFFICER, CLASS II, in the above service. Salary £350, rising by £20 per annum to £600, with quarters, or an allowance in lieu. The pay is subject to a bonus, which at present on a salary of £350 is £135 2s. These posts are pensionable, and there are prospects of promotion to higher rank.

Candidates must be fully qualified and registered. Preference will be given to those who have held House appointments, have had experience in Lunacy and Psychological methods, and are under the age of 30. Forms of application can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

The Otago Hospital Board.

UNIVERSITY OF OTAGO AND DUNEDIN HOSPITAL, NEW ZEALAND.

The post of RESIDENT SURGICAL OFFICER (Senior) will be vacant in August, 1929. Candidates must hold a degree in Medicine of a British University; must have been qualified for three years; and have held resident Hospital appointments for at least one year.

The duties of the successful candidate will be those of superintending house surgeons, with, in addition, certain tutorial work under the direction of the Professor of Surgery.

Salary for the position to be at the rate of £500 per annum, with board and residence.

Full details may be obtained on application to the High Commissioner for New Zealand, Strand, W.C.2.

Otago Hospital Board, Dunedin, New Zealand. May 23th, 1929. JOHN JACOBS, Secretary.

Ministry of Health.

The Minister of Health invites applications from registered medical practitioners (women) for appointment as MEDICAL OFFICER on the staff of the Ministry.

The salary commences at £600 per annum and rises by yearly increments of £25 to £900, and then by yearly increments of £50 to £1,100 per annum. In addition to the salary, a bonus, which varies with the cost of living, is payable; the bonus on the minimum salary is at present £176 7s.

The appointment will be subject to the usual Civil Service conditions as to pension, marriage, holidays, etc.

Candidates must be registered medical practitioners of not less than 7 years' standing and should have had special experience in Obstetrics and of Maternity and Child Welfare work under a Local Authority. Preference will be given to candidates possessing a University Degree in Medicine and a Diploma of Public Health.

Medical Officers are required to devote their whole time to the Public Service and must be prepared to work in any part of England or Wales if required to do so.

Canvassing Members of Parliament or officers of the Ministry will render a candidate liable to disqualification.

Forms of application, with further particulars of the appointment, may be obtained from the Director of Establishments, Ministry of Health, Whitehall, S.W.

No application can be considered unless received on the prescribed form not later than June 25th.

The Prince of Wales's General HOSPITAL, Tottenham, N.15.

Applications are invited for the post of HONORARY ASSISTANT SURGEON to the Ear, Nose, and Throat Department.

Applicants must be Fellows of one of the Royal Colleges of Surgeons, and engaged in Consulting Practice.

June 10th, 1929. FREDK. W. DREWETT, Director.

West Herts Hospital, HEMEL HEMPSTEAD.

(110 Beds. 24 miles from Euston.)

Applications are invited for the appointment of a JUNIOR RESIDENT MEDICAL OFFICER, to commence duties on July 1st next.

Salary £100, with rooms, board, and laundry. Preference given to male candidates.

Particulars to be obtained of, and applications, stating essential particulars, and enclosing copies of recent testimonials, to be sent at once to—

ROBT. L. BUTTERFIELD, Clerk to the Hospital.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculosis and venereal diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Saturday, June 29th. Canvassing, directly or indirectly, will disqualify.

County Hall, Kingston-upon-Thames. June 8th, 1929. DUDLEY AUKLAND, Clerk of the County Council.

Ludlow Union.

APPOINTMENT OF MEDICAL OFFICER FOR THE LUDLOW DISTRICT AND THE LUDLOW UNION WORKHOUSE.

The Guardians of the Ludlow Union will at their Meeting to be held on Wednesday, June 26th, be prepared to consider applications from duly qualified practitioners for the appointment of Medical Officer for the Ludlow District, which comprises the Parishes of Ashford Bowdler, Ashford Carbonel, Bromfield, East Hamlet, Ludford Ludlow, Richards Castle (Herefordshire), Richards Castle (Shropshire), and Stanton Lacy, containing an estimated population of 3,238, with an area of 22,557 acres, and for the Workhouse of the said Union for the term of one year or such other term as the Ministry of Health may fix, with three months' notice on either side.

The salary will be £150 per annum for the Ludlow District and £100 per annum for the Workhouse, exclusive of any extra fees allowed by the General Consolidated Orders of the Ministry of Health, but no fees will be paid for certifying as to Paupers Lunatics in the Workhouse.

The Medical Officer appointed will be required to commence his duties on July 1st next, to reside within the said District, to attend all Paupers therein in case of sickness, to provide all medicines and medical and surgical appliances (except cod-liver oil, quinine, and trusses), generally to perform all the duties of a District and a Workhouse Medical Officer as prescribed by the Ministry of Health, and to contract with the Board of Guardians for the due performance of Vaccination within the said District at the usual fees.

The election will be made subject to the approval of the Ministry of Health.

Applications, stating age, accompanied by testimonials, with evidence of qualification and registration under the Medical Act, 1858, endorsed "Medical Officer," to be sent in to me on or before June 24th.

By Order,

Poor Law Offices, Ludlow. May 29th, 1929. ARTHUR W. WEYMAN, Clerk.

Cumberland Education COMMITTEE.

APPOINTMENT OF ASSISTANT DENTAL OFFICER.

The Committee invite applications for the above post (male or female). Applicants must be fully qualified Dentists. Salary £450, rising to £500 by two annual instalments (subject to deductions under the provisions of the L.G.O.S. Act), with allowance for travelling and subsistence while on duty.

Particulars and forms of application on receipt of stamped addressed foolscap envelope addressed to "The School Medical Officer, County Offices, Carlisle."

June 3rd, 1929. C. W. ALLAN HODGSON, Clerk to the Committee.

Administrative County of Essex.

APPOINTMENT OF MALE ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered medical practitioners specially qualified in the treatment of Tuberculosis, School Medical Inspection, and Maternity and Child Welfare, holding a Diploma of Public Health, and not over 45 years of age.

Preference will be given to candidates who have had at least three years' experience in Public Health work subsequent to their medical qualification. The salary attached to the appointment will be £600 per annum and travelling expenses. The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to reside in such district of the County as the Council may decide. The appointment will be subject to three months' notice on either side.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Monday, July 1st.

Shire Hall, Chelmsford.
June 11th, 1929.

The London County Council invites applications for three appointments, as from October 1st, 1929, as PRINCIPAL MEDICAL OFFICER in its Public Health Department. The duties attaching to the positions will be mainly concerned with general public health work; school medical service; infectious diseases; tuberculosis; children's diseases; administration of hospitals, especially Poor Law Hospitals; and district medical work. Each of the officers appointed will be placed in charge of a division of the Department dealing with branches of the work and will be responsible to the County Medical Officer of Health.

The commencing salary in each case will be £2,000 a year, rising by £100 yearly to £2,500 a year. Candidates must be not more than 55 years of age on October 1st, 1929.

Forms of application, containing full details, may be obtained from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. A stamped addressed envelope should be enclosed and forms must be returned by July 3rd, 1929.

Canvassing disqualifies.

MONTAGU H. COX, Clerk of the Council.

Administrative County of London

The London County Council invites applications for appointment, as from October 1st, 1929, as MATRON-IN-CHIEF in its Public Health Department. Candidates must be fully trained nurses and must have administrative experience of hospital nursing. The principal duties attaching to the position will consist in organising and supervising the nursing staff of the hospitals which will be transferred to the Council under the Local Government Act, 1929. The total commencing salary will be £750 a year, rising by £50 a year to £1,000 a year. Applicants must be not more than 55 years of age on October 1st, 1929.

Forms of application containing full details may be obtained from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. A stamped addressed foolscap envelope should be enclosed. Forms must be returned not later than July 3rd, 1929. Canvassing disqualifies.

MONTAGU H. COX, Clerk of the Council.

Applications, stating age, qualifications, and experience, together with copies of three testimonials, should reach the undersigned on or before Tuesday, July 2nd.

F. P. CARROLL, Secretary-Supt.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain ...	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
„ 18 „ „ „	430
„ 19 „ „ „	460
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	750
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing about the 6th August, 1929.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—MIDLANDS.—PROSPEROUS TOWN.—A one-third share (with increase to one-half) is offered in a very old-established good middle-class Practice averaging £3,400 p.a., including selected panel of over 1,000. M.O.H. and School appts. worth nearly £300. Fees 3/6 to 21/-. Mids. 2 to 10 gns. (20—30 cases yearly). Commodious house, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Can be rented on lease at £65 p.a. Good sport and schools. Premium 2 years' purchase.
2. WESTERN SUBURB.—Well-established increasing PRACTICE, producing for the last 12 months nearly £1,200, including panel of 1,400. Visits 3/6 to 7/6. Good house, containing 2 reception, 8 bedrooms, etc., and professional accommodation. Electric light. Garden. Garage. Can be rented on lease at £130 p.a., or the freehold purchased. Premium £1,800.
3. PARTNERSHIP.—NEAR EPPING FOREST.—A one-fifth share, with increase later, in a well-established and rapidly developing good middle-class Practice, averaging nearly £2,800. Selected panel of about 600. Lowest fee 3/-. Suitable house, with 2 reception, 3 bedrooms, etc., and professional rooms. Can be rented on lease at about £70 p.a. Premium 2 years' purchase.
4. SOUTH COAST.—Popular and Favourite Watering-place.—Old-established increasing mixed-class PRACTICE, producing last year nearly £1,600 (this year to end of May £880), including panel of over 1,150. Visits 3/6 upwards. Mids. from 4 gns. (30 cases yearly). House contains eight rooms, with usual offices and garden. Price for freehold £1,450 (£1,000 at least obtained on mortgage). Held by Vendor over 9 years.
5. EAST COAST.—Popular Resort.—Old-established non-panel better and middle-class PRACTICE, offering excellent scope to a good Surgeon. There is a Hospital with over 80 beds, and prospect of appt. on staff. Average cash receipts for past three years £2,400. Fees 3/6 to 10/6 and upwards. Very little mid. Very good private residence near sea, with ample accommodation. Central Surgery. Premium for prompt sale, owing ill health, only £1,500.
6. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 3/- upwards. Not much midwifery. Low expenses. Very well-situated double-fronted house, with 2 reception, 4 bedrooms, etc., and good professional rooms. Electric light. Garden. Price for freehold £1 5'0. of which £1,000 could remain on mortgage. Premium 1½ years' purchase.
7. NORTH-EAST COAST.—Favourite Seaside Resort.—PARTNERSHIP. A share representing about £1,400 p.a. is for disposal in an exceptionally sound middle and better-class Practice, with increase later. Selected panel of 750. Visits 5/- to 10/6, with mileage extra. Midwifery 3 to 7½ gns.; about 40 cases. Suitable house available. Premium 2 years' purchase. Ingoing partner should be about 30, and have held Hospital appointments.
8. PARTNERSHIP.—SOUTH-WESTERN COUNTY.—In a large seaport town the THIRD SHARE (to commence with) of an old-established mixed-class Practice averaging £3,200 p.a., including panel of over 2,000, is offered. Visits 3/6 to 10/6. Midwifery discouraged; about 30 cases yearly at 3 gns. upwards. Expenses light. Suitable residence available. Premium 2 years' purchase.
9. EAST COAST.—ASSISTANTSHIP with view to PARTNERSHIP.—A one-third share in a very sound mixed-class Practice, producing £2,300 p.a., and offering excellent scope. Panel of about 1,000, and good appointments. Choice of houses. Premium 2 years' purchase.
10. SUSSEX.—PARTNERSHIP.—A one-half share in a very old-established unopposed Practice in delightful district near sea. Average cash receipts for past three years £2,800, including £1,000 from panel and appointments. Visits 3/6 to 42/-. Midwifery from 2 gns.; about 30 cases. Very attractive house, with 2 reception, 6 bedrooms, etc., large garden. Can be rented on lease at £80 p.a. Excellent sport and schools. Premium 2 years' purchase.
11. WITHIN FIFTEEN MILES OF LONDON.—PARTNERSHIP.—A three-eighths share, with increase later, is offered in a well-established Practice in favourite residential district. Receipts average about £3,000 p.a., including panel of 1,500. Fees 3/6 to 21/-. Choice of two houses. Good society, sport, and schools. Cottage Hospital and excellent scope for surgery. Premium 2 years' purchase, part by instalments.
12. MANCHESTER.—PRACTICE is situated in a growing district offering very good scope. Income for the immediate past 12 months over £1,600, including panel of nearly 900. Fees 3/6 upwards. Detached well-situated house, with 3 reception, 5 bedrooms, etc. Can be rented on lease at £110 p.a. Premium 1½ years' purchase.
13. LONDON.—EAST END.—Increasing cash and panel PRACTICE producing £450 p.a., including 300 panel patients. Visits 3/- upwards. Very little Midwifery. Seven-roomed house on lease. Rent £78, inclusive of rates and taxes. Premium £650.
14. WITHIN 50 MILES OF LONDON.—In a small Country Town, in pretty district, a well-established increasing PRACTICE, worth last year over £800, including panel of 525, and appts. about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden. Tennis court. Garage. Electric light. Price for freehold £3,100. Premium 1½ years' purchase. Exceptionally good educational facilities for boys.
15. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, near good town.—Well-established Practice, averaging over £1,000 p.a., including panel of nearly 600. Fees 2/6 to 10/-. Excellently situated house, with 2 reception, 5 bedrooms, etc., and separate entrance to professional rooms. Good garden and garage for 2 cars. Can be rented on lease at £100 p.a. Premium £1,350.
16. CARDIFF. — Good-class old-established non-dispensing PRACTICE, worth last year about £1,350, including select panel of 450. Visits up to 21/-. Very little midwifery. Good house in best part of City, with ample accommodation. Price, freehold, £2,000. Prem. £2,000.
17. FAVOURITE INLAND SPA.—PARTNERSHIP.—A well-qualified experienced gentleman (aged about 40, married, and good at Gynæcology) is required to purchase the half share of an old-established good-class non-dispensing Practice owing to the retirement through ill health of the senior partner. Income about £5,000, including small select panel. Good number of midwiferies. Suitable house available, with ample accommodation, at low rental. Premium 2 years' purchase.
18. SOUTH LONDON (Near CROYDON).—Sound and increasing mixed-class PRACTICE, in growing locality. Gross cash receipts for immediate past 12 months £2,800, including panel of 2,240. Fees 2/6 to 7/6. Convenient freehold house, with electric light. Garage. Garden. Good sport and schools. Premium £4,500. Efficient introd.
19. PARTNERSHIP, with ultimate succession.—SOUTH-WEST LONDON.—A third or half share, to commence with, in an old-established good mixed non-panel Practice, offering large scope. Receipts for last year nearly £2,300. Fees 2/6 to 7/6. *Little midwifery.* Good house, with garden. Can be obtained on long lease at the very moderate rent of £55 p.a. Premium 2 years' purchase.
20. MIDLANDS.—Country district, near large Town.—Agricultural and working-class PRACTICE, *rapidly increasing.* Income last year £1,250, including panel of 545. Visits 3/6 and 5/-. Small convenient house, freehold. Price, including all furniture, excepting linen and plate, £1,650 (£1,000 on mortgage at 4 per cent.). Large garden. Garage. Excellent sport. Premium £1,800.
21. NEW ZEALAND.—(North Island).—In an up-to-date Town (pop. 12,000, with a further 10,000 in outlying district) within 12 miles of the sea, a well-established PRACTICE worth last year over £1,000, including appts. averaging £280. Visits 10/6 to 21/-, *mileage extra.* No dispensing. Excellent Bungalow residence, in an acre of garden, with fruit trees, tennis court, etc., containing 9 rooms, bathroom, etc. Electric light, h. and c. water. Climate finest in New Zealand. Splendid educational facilities and unlimited sport. Scope for surgery.
22. *PARTNERSHIP.—LONDON.*—In a populous district, the half share of an old-established middle and working class Practice, worth over £2,000 p.a., including panel of 1,300. Visits 3/6 to 10/6. Expenses light, car not necessary. House contains professional accommodation, 2 reception, 2 bedrooms, bathroom, etc. Held on lease at rental of about £60 p.a. Premium 2 years' purchase.
23. SHEFFIELD.—Good-class non-panel non-dispensing PRACTICE in best residential district. Average income for last three years over £3,000. Fees 5/- to 21/-. Midwifery 3 to 10 gns.; about 30 cases yearly. Surgery premises can be rented on lease, and contain consulting room, waiting room, 3 bedrooms. Electric light. Garden. Purchaser can choose his own place of residence. Premium 1½ years' purchase, with 1 or 2 years' partnership introduction as required.
24. STAFFS.—LARGE TOWN.—Owing to ill health of present Incumbent, an old-established good-class non-panel non-dispensing PRACTICE is *for immediate disposal.* Income last year over £1,200. Fees 5/- to 10/-. Commodious house, in best residential road. Price for freehold £1,600, part on mortgage. Premium £1,500, £1,000 down.
25. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
26. BORDERS OF NORFOLK AND SUFFOLK. — Very old-estab. good middle-class PRACTICE, averaging over £1,000 p.a., including panel of 530. Visits from 3/6. Easily worked. Very attractive house, modernized, and containing 3 reception, 6 bedrooms, bathroom (h. and c.), separate professional accommodation. Price for freehold £2,000. *Premium £1,500.*
27. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE.—Large Hospital Town within 80 miles of London. A well-established connection averaging nearly £1,000 p.a. (last year £1,059). Patients upper and middle-class. Fees 1½ to 15 gns. House in pleasant position, with ample professional accommodation. Rent £60. Premium £1,500, or offer. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital and successor will be appointed.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

$C_8 H_{10} N_4 O_2 + H_2 O$

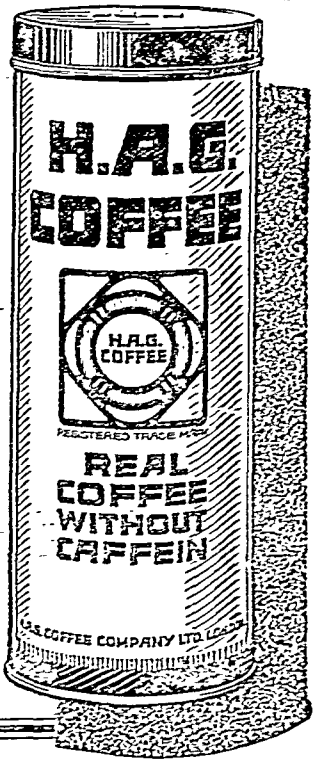
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE,** we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.

The Pre-eminent Vitamin Food

"Bynotone"

"The vitamin problem is of far greater importance than is generally realised . . . . . The vitamin question should first be attended to in the bringing up of infants and young children."—PLIMMER.

"The results of prolonged minor degrees of vitamin deficiency give rise to inferiority in physical development, instability of the nervous system, lack of recuperative power and endurance, and consequent cumulative fatigue and lack of resistance to infection."
McCOLLUM & SIMMONDS.

"Bynotone" is a concentrated nutrient rich in the vitamins *A*, *B* and *D* and other elements which, though often deficient in the ordinary everyday dietary, are of vital importance to nutrition.

"Bynotone" contains essentially—bone marrow, yeast extract, hæmoglobin and liver fat; the latter is prepared by a special process and is the richest known source of vitamin *A*. The natural vitamin content of the ingredients of "Bynotone" is augmented by the addition of a proportion of synthetic vitamin *D*.

"Bynotone" is the ideal accessory food during the ages of active growth and adolescence, the periods of expectant and nursing motherhood and the stage of convalescence after acute disease.

It is a nutrient, hæmatinic and restorative which assists the assimilation of other foods and promotes general good health.

Adrephine

(Adrenalin-Ephedrine Compound)

ADREPHINE provides the rapid, decided, astringent action of Adrenalin when applied to mucous membrane.

To this is added the slow, long-sustained synergistic effect of the true alkaloid Ephedrine obtained from the Chinese plant *Ma Huang*.

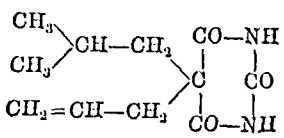
The activity of Adrephine is promoted by reason of an aqueous medium. It may be used to reduce congested turbinates, for aiding nasal ventilation and to promote sinus drainage. Indicated for the treatment of hay fever.

In bottles of 1 oz. and vials of 10 c.c.

PARKE, DAVIS & COMPANY, BEAK ST., LONDON, W.1.

SANDOPTAL

A NEW HYPNOTIC



ISOBUTYL-ALLYL-MALONYLUREA

Clinical and laboratory tests have shown that Sandoptal fulfils to a high degree the conditions required in a hypnotic agent.

Sandoptal owes its advantages to a particularly favourable therapeutic index which permits sufficient dosage without harmful after-effects.

Sandoptal is sure and constant in action, and well tolerated by the aged.

It produces tranquil sleep of natural intensity and normal duration, and the awakening is net and accompanied by a feeling of freshness and general well-being.

It has been shown that Sandoptal is rapidly eliminated from the organism and that it does not produce exanthema.

DOSAGE:

Usual dose: 1 tablet, half to one hour before bed-time.

In obstinate cases: 1 to 3 tablets may be given (maximum dose 4 tablets).

TUBES OF 10 AND BOTTLES OF 100 TABLETS.

AGENCY:

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

THIRD IMPRESSION. Cr. 8vo. 168 pp. 7s. 6d. net; postage 4d.

THE ELEMENTS OF
MEDICAL TREATMENT
By ROBERT HUTCHISON, M.D., F.R.C.P.,
Physician to the London Hospital.

"A model of brevity, clearness, and sound judgement."
—*British Medical Journal.*

ALSO BY THE SAME AUTHOR.
Crown 8vo. 2s. 6d. net; postage 2d.
SOME PRINCIPLES OF
DIAGNOSIS, PROGNOSIS AND TREATMENT

"There can seldom have been more interesting and shrewdly worded advice than that closely packed in these pages."
—*British Medical Journal.*

The Illustrations form a prominent feature of this volume, and much care has been taken to render them as accurately as possible.

SECOND IMPRESSION. Large 8vo. 228 pages, with 251 Illus., some of which are in Colour. 21s. net; postage 6d.
DEMONSTRATIONS OF
PHYSICAL SIGNS IN CLINICAL SURGERY
By HAMILTON BAILEY, F.R.C.S.Eng.,
Surgeon, Dudley Road Hospital, Birmingham.

"It was time a book of this nature was available in English, and the author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which are informative."—*Lancet.*

"An admirable book which we can recommend to all students."
—*Brit. Jour. Surg.*

"We have nothing but praise for this book."—*Edin. Med. Journ.*

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

Overdue Fees!!

NINE-TENTHS of your patients are honest and pay their accounts within a reasonable period; the remaining ONE-TENTH are dishonest (more or less) and do not pay.

It is from the ONE-TENTH that we earn FOUR-FIFTHS of our Income; the remaining FIFTH is paid in advance in the shape of an Annual Subscription.

Why not join the Society now and secure the benefit of the unique organization which has been built up for the collection of unpaid fees

to your clientele?

The unsolicited testimonials we have received confirm all the claims made by the Society.

Full particulars of terms, etc., will gladly be furnished on application to the

BRITISH MEDICAL PROTECTION SOCIETY

ROLLS-ROYCE

The Best Car in the World

"I have heard it expressed that to own a Rolls-Royce car necessitates the employment of a skilled chauffeur. But my own experience is that for the last two and a half years (whilst in the army and now in business) I have looked after my Twenty h.p. Rolls-Royce entirely myself, never allowing anyone even to grease the car. I find that I have to spend about two and a half hours upon it for every two thousand miles run. I have had a considerable experience of cars and as an owner-driver I cannot imagine any car that needs less attention.—*Owner's Letter, ref. 2016*

SURGICAL SERVICE
SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

SALT'S LONG EXPERIENCE IN SUPPLYING SURGICAL APPLIANCES FOR TROPICAL USE

has resulted in an ability to supply specially made appliances in all grades for all climatic conditions.

We therefore draw the attention of Medical Men to our

SPECIALLY LIGHT APPLIANCES FOR SUMMER WEAR

which not only afford the patient an exceptional degree of bodily comfort, but effect real hygiene and economy by allowing the winter appliance to be returned to us for cleaning and rehabilitation.

Excessive perspiration, which so quickly shortens the life of elastic goods, is avoided by the use of

SALT'S OPEN-WEAVE ELASTIC APPLIANCES.

SALT AND SON LTD.

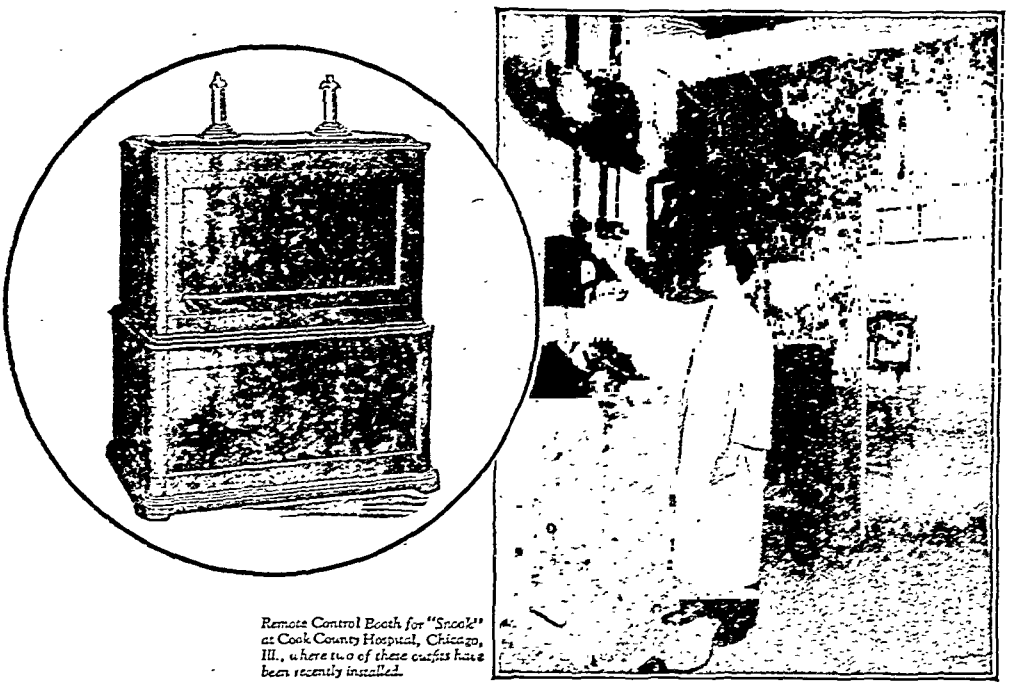
COPYRIGHT



Remote Control Booth for "Snook" at Cook County Hospital, Chicago, Ill., where two of these outfits have been recently installed.

"If others have had as little trouble *with their X-Ray Transformers as I have had in ten years, they must be Snook users"*

THIS is the statement of a roentgenologist who installed a *Victor-Snook* X-Ray Transformer ten years ago, and he adds the information that he is using his Snook "on an average of at least 20 hours a week in treatment work, at 140 K.V. P., as well as for radiography including 100 ma. technic." Says we may give his name to those desiring further information.

A short time ago a questionnaire was sent out covering 150 *Victor-Snook* machines that were installed ten years ago. Up to this writing returns have been received on 132, and it has been extremely interesting to learn not only that all of these are in actual use today, but of the general satisfaction expressed by their users. The outstanding fact brought out through these questionnaires is that the Victor-Snook of ten years ago is equal to the demands of the X-ray art of the present, even with the advanced technics that have been evolved in this decade.

There is only one "Snook."

Full particulars of Snook Transformers gladly sent on request

Now available for every Hospital.

The acme of Simplicity.

The NINETY-THIRTY **X-RAY APPARATUS**

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts at 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy.

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X-ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

PRICE complete, as illustrated, for use on Alternating Current, including all Accessories £350

Ditto, Apparatus for use on Direct Current £410

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of £10.

K.Y. LUBRICATING JELLY

K.Y. Lubricating Jelly reduces the discomfort of instrument-introduction far more efficiently than petrolatum. It is more "slippery," flows more easily, and never binds. It is contained in a convenient compressible tube, which protects it from the air and enables the exact amount needed to be squeezed out quickly and hygienically. K.Y. Jelly is greaseless, non-staining, and water soluble. It is prepared from certain vegetable substances blended in correctly balanced proportions with boric acid, and does not irritate the skin or interfere with the application of local remedies.
Obtainable from medical supply firms and pharmacists throughout the world.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the cosmic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Intestinal Disinfection

RHEUMATOID ARTHRITIS

UNDER this name, several conditions which are ætiologically distinct are doubtless grouped together, and we are still far from a solution of the cause of the disease.

It is obviously impossible to restore in any marked degree mobility to the joints of the hopelessly crippled, but in the early stages much may be done to retard or stop the progress of the disease.

An eminent surgeon has directed attention to the rôle of chronic intestinal stasis and alimentary toxæmia in the production of the disease, and has emphasised the need for intestinal disinfection.

For this purpose nothing surpasses the use of Kerol Capsules. Kerol is a potent and non-toxic germicide which is unabsorbed from the intestine, so that the whole of its germicidal power is exerted upon the contents of the bowel.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

MESSRS. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

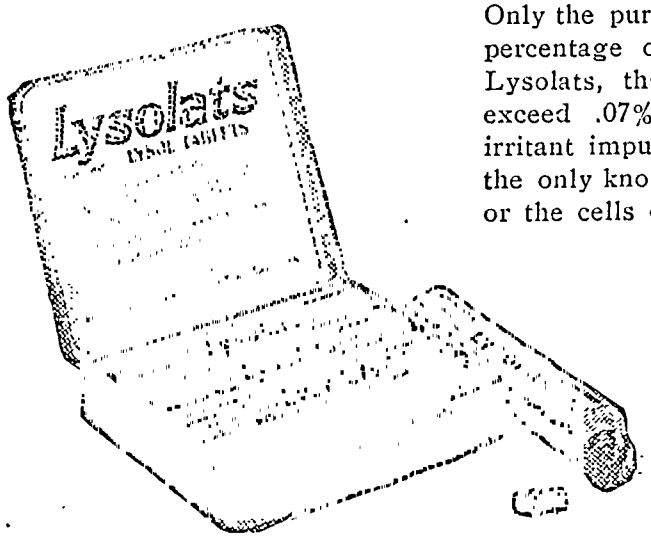
DINNEFORD and Co. LTD.

The Solid Form of Lysol contains the Highest Grade of Cresylic Acid

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

In emphasising the care necessary in the choice of a lysol, the makers of Lysolats are repeating a warning that has been made time and again by medical men. The cresylic acid used in the cheap liquid lysols is often deficient in Meta-Cresol, which, as doctors know, is the most actively bactericidal of the isomers.

Only the purest grades of cresylic acid containing a high percentage of Meta-Cresol are used in the making of Lysolats, the solid form of lysol. Impurities do not exceed .07%, including water. The absence of these irritant impurities is one of the reasons why Lysolat is the only known antiseptic that is non-toxic to the plasma or the cells of the human tissue.



Lysolats
PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

LIVER EXTRACT B.D.H.

The success that has attended the use of liver in cases of pernicious anæmia has stimulated further medical research upon the subject, and recent findings foreshadow liver therapy as an asset in the treatment of secondary anæmias also, such as those resulting from chronic hæmorrhages.

In view of the consequent increased demand the need is emphasised for the use exclusively of products of guaranteed potency. Liver Extract B.D.H. is such a product; it is made by a process which has been tested and approved by the Medical Research Council. Physicians prescribing it ensure for their patients a reliable preparation of constant potency which produces maximum clinical effects.

Liver Extract B.D.H. is a freely-running powder containing in small bulk the active principles of fresh liver. It is very palatable as a beverage made with water, soup or milk; alternatively it can be sprinkled on toast, bread or potatoes as a savoury.

Liver Extract B.D.H. is issued in glass tubes, each containing the therapeutic equivalent of ½ lb. of fresh raw liver, the maximum daily dose.

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat."

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition :—

	Dry Food		Reconstituted (1 part in 8 parts of water)
Fat - - -	15.5	... ...	1.7
Proteins - -	20.0	... ...	2.2
Lactose - -	58.0	... ...	6.4
Mineral Matter -	4.5	... ...	0.5

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods.

COW & GATE Ltd.,

GUILDFORD.

The most efficient Peptonising Powders!

Half a tube of Benger's is enough!

While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1—Box of 6, 1/-; No. 2—Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

Prices: 3/-, 5/6 and 10/6

Medical men may obtain full particulars of Benger's preparations post free on request.

BENGER'S Food

HEWLETT'S ORIGINAL PREPARATIONS.

ANTISEPTIC CREAM

(Cremor Antisepticus)
(HEWLETT'S)

A delicate antiseptic emollient healing Cream, instantly relieving the itching and burning sensation of the skin in cutaneous diseases. Its healing and soothing properties are widely recognized in the treatment of Wounds.

Price, in Collapsible Tubes 18/- per doz., or 5, 10, 22, 40, and 90-oz. Jars, 5/6 per lb.

GARGAR. FORMALIN CO.

(HEWLETT'S)

A most economical, efficient, and pleasant gargle and mouth wash, containing Formalin, Glyc. Acid Carbolic, Tinct. Pyrethri, etc., suitably flavoured. It is highly concentrated, one fluid drachm being sufficient for an eight ounce bottle.

PRICE 5/6 PER LB.

"Please supply us with a two pound bott'e of Gargarisma Formalin Co.' We have tried a small quantity and find our patients like it."—L.D.S.Eng.

HORMONIGEN

(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE: HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

MIST. SENECIO CO.

(HEWLETT'S)

An elegant and effective combination of Senecio, Hydrastis, Pulsatilla, and aromatics which has proved very efficient in Amenorrhœa, Dysmenorrhœa, and Menorrhagia. The compound has a most beneficial effect in Dysmenorrhœa, relieving the pain and regulating the flow. In acting more particularly on the uterine nerves, it is of special value in the non-inflammatory form of Dysmenorrhœa. When anæmia and chlorosis are present, iron is an essential part of the treatment; but MIST. SENECIO CO. is useful as a general uterine and nervine tonic.

PRICE 12/6 PER LB.
In 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

VERONIGEN

(Formerly known as MIST. VERONAL CO.)
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10/6 PER LB.

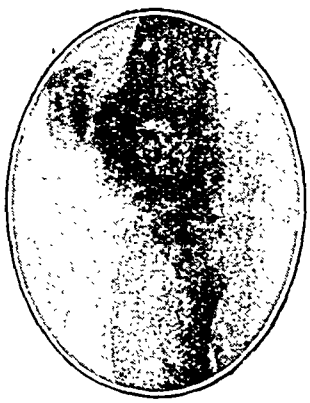
'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



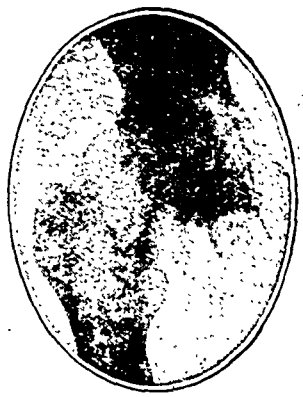
Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.



Radiograph of Hip-joint in Rheumatoid Arthritis

INSULIN 'A.B.'

TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.

Supplied in two strengths:

20 units per c.c.
Packed in bottles containing:
5 c.c. (100 units or 10 doses) 2/- each
10 c.c. (200 „ 20 „) 4/- „
25 c.c. (500 „ 50 „) 10/- „

40 units per c.c.
Packed in bottles containing:
5 c.c. (200 units or 20 doses) 4/- each

Full particulars and the latest literature will be sent free to members of the Medical Profession.

LIVER THERAPY
IN
ANÆMIA

The efficacy of treatment with Liver or Liver Extract in cases of Pernicious Anæmia is now recognized. The blood picture rapidly returns to normal and apparently remains so indefinitely while the treatment is continued. It still remains to be seen whether permanent cure is possible, but it is known that usually, when the erythrocyte count has been raised to a satisfactory level, a reduced dosage will protect the patient against relapse. Liver therapy is also effective in certain cases of Secondary Anæmia, especially when due to failure of blood regeneration after hæmorrhage. This effect is greatly enhanced by simultaneous administration of iron.

HEPATEX

This is the liquid extract of liver made at Evans' Biological Institute, the method of preparation ensuring that the whole of the therapeutic principles are contained in the final product. Being concentrated so that 1 oz. equals 1 lb. of fresh liver, it is the most convenient form of liver extract for oral administration. It has been tried clinically with notable success.

Supplied in 4 oz. bottles at 12s. per bottle.

Each bottle contains sufficient for 8 days' full treatment

Prepared at Evans' Biological Institute, Runcorn.

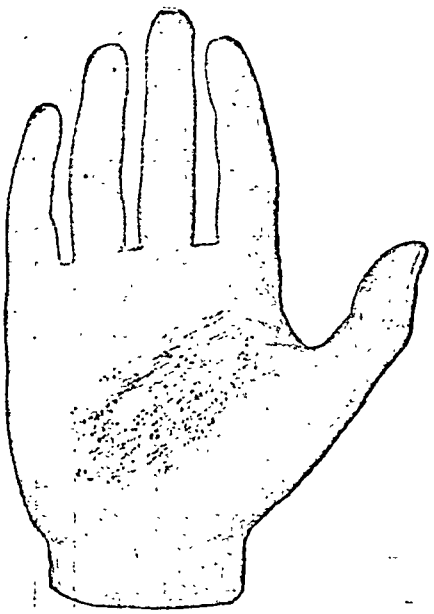
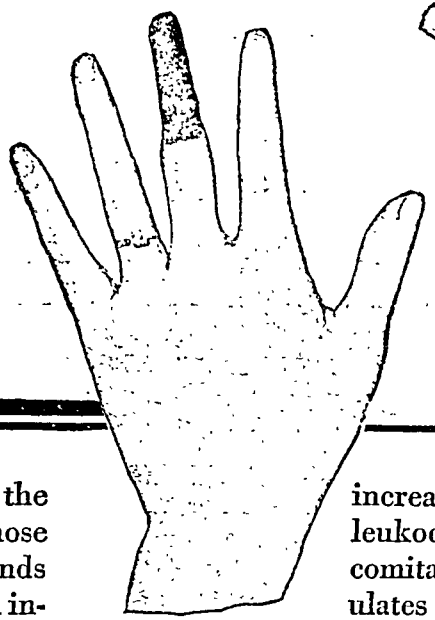
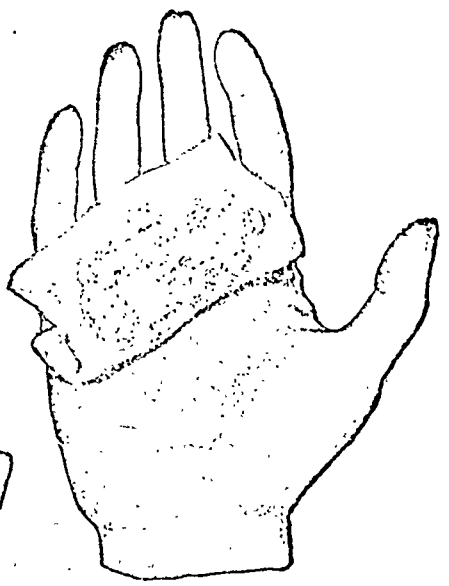
Positive Chemotactic Action!



Contused wound of hand, with emery ground into the wound.



Carbolic acid gangrene of finger. Result of wrapping in cloths saturated with 5 per cent carbolic acid.



Same hand after removal of the Antiphlogistine dressing.

IN infections of the hand and in those accidental wounds associated with bacterial invasion of the body, the application of Antiphlogistine means *fortified resistance to infection plus rapid regeneration of damaged tissue.*

The immediate effect of an Antiphlogistine dressing is to induce an active hyperemia and relaxation of the smaller arteries, bringing into the involved tissues a greater number of leukocytes in proportion as the volume of arterial blood is increased. The advent of leukocytes and the concomitant leucocytosis stimulates the blood-forming mechanism to greater activity and hastens the new formation of fixed tissue elements upon which the entire healing process depends.

The application of Antiphlogistine, through the induction of active hyperemia, constitutes a kataphylactic procedure which is both leukocytagogic and seragogic in its physiological effects. In short, Antiphlogistine is Nature's synergist.

Antiphlogistine

is a scientific antiphlogistic, supporting and augmenting the defensive mechanism of the body at every stage of the inflammatory or infectious process.

EXAMPLE OF CHARACTERISTIC EARLY INDIAN ARCHITECTURE: THE *STŪPA* FROM WHICH WAS EVOLVED THE HINDOO TEMPLE.—The most important outward testimony to the work of the pioneers of civilisation in ancient India is to be found in architecture, to which all other arts are accessory. Indian architecture springs out of religion, but not primarily from Buddhism: it has its roots in Indo-Aryan beliefs and ritual, as we know them in the Vedas. In Vedic times, the *stūpa* or *tope* (Hindoo *tope* from Sanskrit *stūpa*, a mound) was the tomb of a king or chieftain, and the form in which it survived was originally the tumulus. It then became a religious symbol used to mark sacred places. The *stūpa* here reproduced shows its usual form. It consisted of a solid structure of bricks laid in a cement of mud, with an outer facing of dressed stone overlaid with cement. The railing originated in the wooden fence which enclosed the Vedic sacrificial area; within it was the Path of Auspiciousness, perambulated by the pilgrims. The four gateways mark the cardinal points. Later, the *stūpa* became the central portion of a church, at the junction of nave and aisles. The *stūpa* itself belongs to the time of Asoka; the gateways and sculptures appear to have been added a little later.

Agarol Brand Compound is the *original* mineral Oil — Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

A British Medical Association Lecture
ON
DIFFICULT LABOUR.*

BY
R. W. JOHNSTONE, C.B.E., M.A., M.D., F.R.C.S.Ed.,
PROFESSOR OF MIDWIFERY AND THE DISEASES OF WOMEN, EDINBURGH UNIVERSITY.

EVERYONE with obstetrical experience will agree that the commonest cause of difficulty in labour is the occipito-posterior position of the vertex. Probably the second most frequent cause is breech presentation.

OCCIPITO-POSTERIOR PRESENTATIONS.

Considering how small is the deviation from the normal, the amount of trouble and worry which occipito-posterior positions cause is astonishing. Difficulty, of course, arises mostly in those cases in which the occiput fails to rotate spontaneously to the front, and this is due mainly to a lack of complete flexion of the head. It is elementary knowledge that an imperfectly flexed head throws larger diameters across the pelvis than a completely flexed one, and in the case of occipito-posterior positions this results in, first, late engagement of the head at the brim of the pelvis; secondly, a tendency to arrest and impaction of the head when it is in the cavity; and thirdly, great difficulty in the birth of the head, face to pubes.

The late engagement or arrest of the head at the brim, which occurs in some occipito-posterior cases, is largely due to the wide posterior part of the head trying to get into the pelvis through the sacro-cotyloid diameter, which is rather small for it. An important corollary is that this arrest of the posterior part of the head tends to a still further undoing of flexion and a consequent increase in the antero-posterior measurements of the head thrown across the pelvis. The degree of misfit which is thus present between the presenting part and the brim of the pelvis may lead to the membranes protruding through the partially opened os in a sausage shape; and, as always, such membranes are peculiarly liable to early rupture. Cases, therefore, in which there is considerable arrest of the head at the brim of the pelvis are often further complicated by the labour becoming a dry one. The result in such cases is a prolonged and painful first stage, dragging on hour after hour and it may be day after day, with intervals during which the pains, in some cases never properly efficient or regular owing to the lack of proper pressure by the head and the bag of membranes upon the region of the internal os, tend to cease altogether.

In time, however, the cervix becomes completely dilated and the moulded head slowly passes down through the pelvis, delay being experienced throughout, owing to the large diameters of the head. The crucial point is when the head reaches the pelvic floor. Where the flexion has been complete and the first stage more or less normal, the occiput rotates to the front without any great difficulty, but in the cases which we are considering, where flexion is imperfect, there is often great delay in the occurrence of rotation. In many cases the head remains in the oblique diameter of the pelvis simply because the uterus has become too exhausted to cause rotation; in other cases the deflexed head becomes impacted upon the ischial spines, while in still others, in which the degree of deflexion is even more marked, the sinciput becomes the leading part of the head, and is rotated to the front, while the occiput slips into the hollow of the sacrum. Delivery with the head in this position involves the passage through the outlet of the pelvis of diameters which are probably from a half to three-quarters of an inch longer than in a normal labour, with the consequence that great force must be exercised either by the uterus or by the forceps, and that a deep tear of the perineum is almost inevitable. All of us have experienced cases illustrating difficulty at any or all of the stages I have mentioned, but it may be helpful to consider them calmly in an atmosphere more judicial than the lying-in chamber.

* Abstract of a lecture delivered before the Blackburn Division on February 27th.

Diagnosis.

Before making any remarks with regard to treatment I must refer to diagnosis, because every year's increasing experience has brought it home to me that failure to recognize the occipito-posterior position is a more fruitful source of worry and suffering and disappointment than almost any other diagnostic error in midwifery practice.

Ante-natal examination will, in most cases, reveal the occipito-posterior position. The method of examination is abdominal and depends in the main upon failure to recognize the continuous resistance of the back running down the front of the uterus on one or other side of the middle line. Secondly, the small parts of the foetus are palpable with ease on both sides of the middle line. Thirdly, the trunk of the child may be felt well round to one or other flank, usually the right. Fourthly, the foetal heart is best heard well round to the flank, but may sometimes be heard also anteriorly on the opposite side of the abdomen. This last is a point of importance, as it indicates that the child is lying with its spine straightened and its chest thrown forwards, and this implies a degree of undoing of the flexion of the head.

Owing to the difficulty which the head, especially if incompletely flexed, may have in entering the brim of the pelvis, it tends to remain movable above the brim, even in a primigravida, until the commencement of labour. Failure of the head to engage in the brim of the pelvis at least a fortnight before labour in a primigravid woman should always make one think hard, and lead, if necessary, to revision of the pelvic measurements; but if these are quite satisfactory, then the posterior position of the head is enough to account for the failure to engage. Up to about five or six weeks before full time the child may quite readily change its position spontaneously, and come to lie occipito-anterior; but it rarely changes within the last fortnight, indeed comparatively seldom within the last month, and I think that cases of occipito-posterior position diagnosed in the later weeks should be treated by an effort to correct the position.

The only method that I know which affords any prospect of success is the one described by Dr. R. C. Buist of Dundee. The patient is asked to come back, bringing with her two pillow-slips and a bolster-slip. One pillow-slip is folded into a firm cylindrical pad or roller, which is then placed on the right flank (I am assuming a right occipito-posterior position in this case), in order to press the anterior shoulder of the child towards the middle line. The other pillow-slip is folded in four and placed as a firm pad on the left side of the lower abdomen to press back the limbs of the child, while the bolster-slip is fixed as a firm abdominal binder to keep the pads in position. The patient is then told to go home, to rest as much as possible during the next forty-eight hours, and to take a dose of castor-oil the morning after the pads have been applied. In a series of close upon a hundred cases, regarding which careful notes were taken in our ante-natal department, Haultain[1] found that the occiput rotated to the front in rather over 80 per cent. Once it has come round to the front the head tends to engage, especially if a firm binder be kept in position to press it into the pelvis, and relapse cannot occur. After the head has begun to engage with the occiput posterior, any attempt to rotate it by means of pads is, of course, useless, and the first stage of labour must be allowed to complete itself before any question of intervention arises.

During labour the diagnosis can again be made by the abdominal method, but an aseptic vaginal examination will further confirm it. The main point here is the recognition of the anterior fontanelle lying to the front, and it is important to try to feel also the posterior fontanelle, usually pretty high up in one or other posterior quadrant of the pelvis, and to attempt to assess the relative levels of the two fontanelles. This gives one an idea of the degree of flexion of the head. If, at the end of the first stage, there is still any doubt as to the exact position of the head, the point can be settled beyond all question by feeling the ear of the child. The one or two fingers which are sufficient to make the vaginal examination in a normal case are quite inadequate in an abnormal case. The secret of correct diagnosis in all cases of difficult labour is

"chloroform and the whole hand." Under anaesthesia, and with aseptic precautions, the hand is slipped up the side of the head until the ear is felt, and when it is flattened out on the head, the pinna points towards the occiput. The importance of this method of diagnosis is very great, because, as I have already indicated, so many disasters result from allowing the case to drift on without the attendant having an accurate knowledge of the position of the head, and therefore of the real cause of the delay.

Difficulties are likely to be encountered only where the head is imperfectly flexed; if, therefore, we can at a comparatively early stage recognize that we are dealing not merely with an occipito-posterior presentation, but with an imperfectly flexed head, then we are in a position to consider whether or not early intervention is advisable. Signs which point significantly to imperfect flexion are, first, delay in the engagement of the head; secondly, sausage-shaped membranes; thirdly, rupture of the membranes early in the first stage; fourthly, ability to hear the foetal heart through the chest of the child; and fifthly, the anterior fontanelle lying on a lower level than the posterior, as felt by vaginal examination. Look at this table, based upon an analysis by Miller[2] of over 750 cases of occipito-posterior positions in our hospital work in Edinburgh.

Signs of Imperfect Flexion.	No. of Cases in which Noted.	Termination.	
		Malrotation or Non-rotation.	Spontaneous Forward Rotation.
Early rupture of membranes ...	197	145 (74 %)	52 (26 %)
Delayed engagement of head ...	139	107 (77 %)	32 (23 %)
Foetal heart heard anteriorly as well as in flank	103	78 (76 %)	25 (24 %)
Two or more of above signs noted	141	81 %	19 %
Normal engagement, and rupture of membranes near full dilatation of os. Heart not heard in front	332	33 (10 %)	299 (90 %)

The moral to be drawn from this table is that if we can definitely recognize a lack of complete flexion from the presence of two or more indications we may justifiably and advantageously intervene early, in the interests of both mother and child; experience tends to show that when intervention has to be undertaken late in labour both patients are more exhausted, and the actual intervention itself is more difficult.

Management.

I am no advocate of unnecessary intervention in labour—very much the contrary, indeed. In the great majority of occipito-posterior cases the occiput will rotate to the front, if given sufficient time; it is only where one has definite evidence that in a given case the head is so deflexed that it will probably not rotate spontaneously to the front that I think one should intervene early. Such cases will probably form only from 10 to 20 per cent. of all occipito-posterior presentations. The method of intervention indicated is manual rotation, and with the head at the brim this is an easy operation. It is important to visualize exactly what we propose to do before the hand is introduced, just as in a case of internal version. Without this precaution, we may find ourselves attempting the operation in a strained attitude or with the hand which is obviously less convenient than the other hand would have been. It is important to try also to rotate the body of the child by external manipulation, and this can be helped in many cases by grasping the anterior shoulder between the tips of the first and second fingers *in utero*, while the palm of the hand is spread over the side of the child's head, and actually produces rotation of the head. Some authors have, I think, exaggerated the risk of rotating the child's head without the rotation of the shoulders. The child's neck is capable of rotation without injury to an extent considerably beyond the capacity of the adult, and I have again and again rotated the head without succeeding in rotating the body, and the child has been in no way affected. At the same time, it is certainly desirable to make every effort to rotate the shoulders, and there is a greater likelihood of the head going back to its original position if the shoulders are not turned.

When we come to the question of the arrest of the head on the floor of the pelvis we have to decide whether to attempt to rotate or to deliver by forceps as a face to pubes case. I confess that I very much prefer rotation to forcible delivery face to pubes; indeed, I think that to deliver a child of normal size as a face to pubes case should be regarded either as a failure in diagnosis or as a confession of failure in efforts to rotate. It is the most undesirable method of all, because it inevitably necessitates undue force and laceration. With regard to the methods of rotation, manual rotation is much safer than forceps rotation. Rotation of the head in the cavity is not, as a rule, a difficult matter. All that is required is that the head should be gently pressed back a little so as to undo any actual impaction; flexed, if possible, so as to throw smaller diameters across the pelvis; and then, if the side of the hand is spread out over the side of the head, a mere movement of rotation of the hand will produce a corresponding rotation of the head. As before, a similar effort should be made to rotate the shoulders by external manipulation through the abdominal wall. Lastly, in this connexion, we must not forget that, although the position is unquestionably the rarest of all, yet the left occipito-posterior position does exist. Therefore, if difficulty is found in trying to rotate the occiput round the right side of the pelvis, an effort should be made to rotate it round the left side before giving up manual rotation as impracticable. Should manual rotation fail, then forceps rotation, provided great care is used to avoid injury to the maternal soft passages as well as to the child's head, is a useful method of treatment. One of the secrets of success is to sweep the handle of the forceps gently and slowly round the arc of a considerable circle, so as to reduce to a minimum the movement of the blades inside the pelvis.

Where rotation has been effected by hand, the head should be well pressed down on to the floor of the pelvis by fundal pressure, and the remainder of the labour either left to nature or shortened by forceps, as circumstances indicate. When the head has been rotated by forceps, then I think that the rest of the delivery should also be conducted instrumentally by the rapid reapplication of the instruments with the blades in their proper position.

In cases where the delivery, for one reason or another, is being conducted face to pubes, and where considerable tearing is likely, I strongly advocate the deliberate incision of the perineum—that is to say, an operation of episiotomy. Personally I prefer to make this incision in a postero-lateral direction, so that any extension of the incision will avoid involvement of the anal sphincter. The subsequent stitching of a clean cut like this is very much easier, and the anatomical restoration of the parts simpler than in an irregular laceration, while the additional room which it gives shortens very materially the later part of the delivery.

BREECH PRESENTATIONS.

The next most common cause of difficult labour is, I think, breech delivery, and an analysis of the complications and difficulties which we have met in recent hospital experience of 233 breech deliveries in three years clearly indicates that the main causes of trouble are the impaction of the breech, especially in cases of frank breech, and, secondly, arrest of the after-coming head, due either to imperfectly dilated passages or to some undoing of the flexion of the head by pulling on the limbs. In these 233 cases we had 8 maternal deaths, but in only one could death be attributed even indirectly to the nature of the labour—a death from septicaemia following impaction at the brim. All the other 7 cases were very seriously complicated by eclampsia (2), concealed accidental haemorrhage (2), acute rheumatic fever, acute pulmonary oedema, and grave cardiac disease with heart failure. The foetal mortality (78) in these 233 cases varied from 3 per cent. in one year to 18 per cent. in another, after complications such as placenta praevia, contracted pelvis, accidental haemorrhage, extreme prematurity, etc., had been deducted.

I am not able to explain the great difference in different years. It may just be a matter of good or bad fortune, but it is quite possible that it is an indication of the skill of the house-surgeon at the time, because it is a well-known fact that the foetal mortality in breech cases depends in considerable measure upon the knowledge, skill, and presence of mind of the obstetrician.

The greatly increased difficulty and danger, especially to the child, in a breech case in a primigravida is so well recognized that we invariably make an effort to correct this malpresentation where it is met with in such patients in the ante-natal department. During the three years in which we dealt with these 233 cases there were to our knowledge an additional 44 cases so averted by external version.

Management of Breech Labour.

With regard to the general management of breech labour I have nothing to say that is in any sense new, but some points in the old and sound teaching may bear repetition. Masterly inactivity in the early stages is unquestionably the keynote of success. My old master, Sir Halliday Croom, used to sum it up in the words, "Hands off the breech," and this certainly may be said to summarize the whole management of a normal breech case up to the birth of the lower limbs. Frank breech cases always tend to give more trouble than those in which the attitude of the child is one of complete flexion. The extended legs act as splints to the trunk and prevent the lateral flexion of the trunk, which is an essential feature in the descent of the breech through the pelvic outlet. Impaction of the breech is therefore very liable to occur when it reaches the pelvic floor, and artificial assistance is often needed. This usually takes the form of bringing down one or sometimes both legs, and the fact that this diminishes the bulk of the breech as it passes through the outlet of the vagina, and that the soft passages are therefore not so completely dilated as they would otherwise have been, leads not infrequently to subsequent difficulty in the birth of the head.

In the 233 breech cases we had 21 cases of frank breech. Artificial assistance of one sort or another was required in 20 of these—that is, in over 95 per cent. The assistance took the form, in most instances, of extraction of the breech after bringing down a leg, and in 7 of these cases an episiotomy was performed in order to give more room for manipulation. No maternal deaths occurred, but 7 stillbirths—that is to say, a foetal mortality of 33 per cent. in this particular set of cases. The cause of death was cerebral haemorrhage in 4 instances, and asphyxia in 2, while one child was dead *in utero on admission of the mother to hospital.*

Treatment of Impaction.

This leads me to speak briefly of the treatment of impaction. If it occurs at the brim, the cause is almost always either the mere bulk of the breech or a contracted pelvis; if it occurs when the breech has reached the pelvic floor, the cause is usually a frank breech. With the breech at the brim, the treatment is to push the breech gently out of the pelvis and to bring down one foot, the foot lying anteriorly by preference. Unless there are definite indications for the rapid completion of the labour it is much safer for both patients to leave Nature to drive the half-breech slowly through the pelvis rather than to proceed immediately to the extraction of the child. To overcome the impaction is usually all that is needed, and intervention at this stage should preferably stop there.

When the impaction occurs at the pelvic floor—due usually to a frank breech—an attempt may be made to hook down the breech by passing the finger into the groin. The breech hook should be used only if the child is dead. No great degree of force can be exercised by the finger or fingers in the groin, and, if we fail, we may sometimes succeed in extraction by the use of forceps; but the grip is not a very satisfactory one, and I d rd the breech as at all a good indication for the I believe that better results follow if, wi in the Sims position, the breech is gently pr brim and one foot is brought down as bef doing this is undue stretching of the lo ment, but if the patient is deeply ana the manipulation is gently and slowly done, the risk is not great.

When intervention is required for the extraction of the *after-coming head or for the bringing down of a displaced* arm, the great danger is that the obstetrician may become flurried. It is perfectly true that there is no time to lose, but it is equally true that "the more hurry, the less speed." To be successful the intervention must be carried through exactly according to the book. I say this because, to the man who is anxious and flurried, and who dreads that he is going to have a stillbirth, the temptation to pull, in the hope that with a little extra force he will be able to extract the head, although it may be partially extended, or although one arm or even two may be displaced alongside it, is almost irresistible. The sooner that man realizes that in such an effort he is wasting valuable time and endangering the child's life, and that there is no road to success except the high road, the better for his obstetric practice. Two other small points in this connexion are: first, that no attempt to bring down an arm should *be made until the trunk is born as far as the scapula—in* other words, the arm must be brought well into the cavity of the pelvis and within reach, otherwise the attempt to get it down will fail; secondly, that in a case where intervention is hindered by a tense perineum, and in all cases of a primigravid breech labour, an episiotomy ought to be made, because the additional room which it gives is an enormous advantage in the necessary manipulations, and in the subsequent birth of the head.

Lastly, the Prague seizure is generally to be condemned as a crude and somewhat brutal method of extraction, in which one has little control over the force exerted. It is not comparable in efficacy with the Mauriceau-Smellie grip with the child astride the forearm and two fingers placed well back over its tongue. The essence of the manœuvre is to produce flexion of the head simultaneously with the extraction, and this can unquestionably be best *brought about by the fingers on the tongue pulling down* the face, while the occiput is forcibly lifted up against the symphysis pubis in the movement of extraction.

The After-coming Head.

The application of forceps to the after-coming head is a method of treatment which is more ignored than it deserves to be. If the forceps are sterilized and ready, it does not take more than a few moments to apply them to the after-coming head with the trunk and limbs of the child swung well forward and out of the way by an assistant; and there is no question that the forceps give a degree of control over the movements of the head which is greater than that obtained even in the Mauriceau-Smellie manœuvre, while the application of the force to the head and not to the neck is probably safer for the child. I always like to have forceps ready in a breech delivery, and I have found them *a most satisfactory means of delivering the after-coming* head. Herman described it, without qualification, as "the best treatment where help is needed in the delivery of the after-coming head."

From the figures I have already quoted with regard to stillbirths in frank breech cases, it will be seen that cerebral haemorrhage is one of the commonest causes of death. This exceedingly important observation is based on the incontrovertible evidence of a large series of post-mortem examinations. The haemorrhage is due in most cases to tears in the ligaments of the brain, the falx cerebri, and, in breech cases especially, the tentorium cerebelli, and the injury to these structures is unquestionably due to the fact that in the rapid extraction of the after-coming head the skull is exposed to rapid changes of shape, putting a sudden strain upon its internal structures which they are incapable of sustaining. In a head-first labour the slow moulding of the head allows very considerable changes in the shape of the head to occur with corresponding damage, but this is simply beca moulding forces are applied so slowly. As frequency of these intracranial injuries examination of the bodies of 16 infants *breech, found such injuries in no f* Heidler, in a recent examination breech deliveries, found tears

11 he found death to be due to asphyxia, while in the remaining 20 cases the skull was not dissected, so that no actual diagnosis was made. Browne, on the basis of an examination of 200 stillbirths in the Edinburgh Maternity Hospital, showed that cerebral haemorrhage was ten times more common in breech than in vertex cases.

The moral to be drawn from these observations is that intracranial injuries resulting from the rapid extraction of the after-coming head are a considerably greater source of danger to the child than is asphyxia from delay in the birth of the head. It is generally accepted that the foetus can exist for at least ten minutes without receiving fresh supplies of oxygen. Bourne, in his valuable little book, *Recent Advances in Obstetrics and Gynaecology*, refers in this connexion to the apnoeic condition of children born after a prolonged period of "twilight sleep," and who, if left severely alone but merely kept warm, remain motionless for perhaps ten minutes or a quarter of an hour while the heart beats quite regularly, and then quietly and gradually establish respiratory movements. As one who uses "twilight sleep" to a large extent, I have had a great many instances of this, and I can confirm it absolutely. But the application of the matter at present is that it emphasizes the need for care and deliberation in the extraction of the head, and the danger of "hurry."

White Asphyxia.

Many of you will have read recently in the *British Medical Journal* a short correspondence which followed a letter by Mr. Bourne in regard to the pallid form of asphyxia—and that is usually the only serious form. With the main burden of Mr. Bourne's letter I am in entire agreement. There is far too much done in the way of violent efforts at resuscitation of the asphyxiated child, and there is no question in my own mind that in many cases the child who is in this condition of suspended animation actually has the flickering spark of life extinguished by these misguided efforts. Clearing out the mucus and liquor amnii from the throat by means of a soft rubber suction tube, warmth to the surface of the body, and a little old brandy on the gums and palate, and in severe cases the intramuscular injection of one or two minims of pituitary extract, have in my experience proved most successful. The main general point to remember is, however, that infants who pass into a condition of white asphyxia are suffering from a condition akin to shock, and should be treated along appropriate lines, warmth and extreme gentleness of handling being the essentials.

THE TREATMENT OF EXOPHTHALMIC GOITRE

BY

CHARLES S. D. DON, M.D.Aberd., M.R.C.P.Lond.,

HONORARY ASSISTANT PHYSICIAN TO SALFORD ROYAL HOSPITAL.

The controversy which centres around the treatment of exophthalmic goitre is largely due to the fact that patients may get better without treatment. These recoveries are too often attributed to some particular line of treatment, which is then hailed as having the power to effect a cure in a substantial percentage of cases; thus numerous procedures have been advocated, all of which were said to produce good results. Until recently the physician alone showed any interest in the disease, and in his treatment he often adopted a rather fatalistic outlook. He insisted on the removal of all septic foci, advocated a diet in which meat was restricted, advised rest, prescribed sedatives, and if the case was not improved then, the disease had to be left to Nature. Serums, vaccines, and numerous lines of treatment have all been tried, but to-day the most popular remedies are (1) rest combined with iodine, (2) *x*-ray therapy, (3) operative procedures.

In this paper an attempt is made to compare the results obtained from these three lines of treatment, and in diagnosis, and in estimating improvement or otherwise, I have relied on the basal metabolic rate, the pulse, and the weight; the element of personal bias is thus eliminated and the results are probably rendered more acceptable. In calculating the basal metabolic rate the Douglas bag and Haldane gas analysis apparatus have been used exclusively.

In deciding whether a patient has exophthalmic goitre or not the view is adopted that there must be in every case an increased basal metabolic rate in addition to the usual signs and symptoms. There is a small group of women between the ages of 40 and 45 who show some signs and symptoms of exophthalmic goitre but in whom the basal metabolic rate is not increased; these are therefore not included in my cases. Cases of toxic adenoma are also omitted.

Treatment with Iodine.

The possibilities which treatment with iodine held out were first appreciated by Marine and Lenhart[1] when they found that the goitre in Graves's disease contained less than the normal amount of iodine. Ten years later Neisser[2] gave small doses of iodides to patients, and reported good results. These results were supported by the observations of Beebe,[3] using small doses of iodine, and by Loewy and Zondek,[4] who prescribed 3 drops of a 5 per cent. solution of potassium iodide. This they increased to 20 drops three times a day so long as the weight continued to increase.

We owe most of our knowledge to Plummer,[5] who reported the results of 43 cases in which Lugol's iodine was used; he found that 95 per cent. were benefited. He stated that the basal metabolic rate was considerably reduced, though only temporarily, in most of his cases in about ten days; this was confirmed by Cowell and Mellanby[6] in this country.

I have observed the effects of iodine in 36 cases, paying special attention to the basal metabolic rate, pulse, and weight. No case is included in which the basal metabolic rate was under +30 per cent., while in the most severe case there was a basal metabolic rate of +114 per cent. In 31 of these cases iodine was being given for the first time, and the drug prescribed was usually Lugol's iodine in doses of 20 to 30 minims a day. In 8 cases the basal metabolic rate and pulse rate were reduced to within normal limits; in 18 other cases there was marked improvement, but the basal metabolic rate and pulse were still raised. In 4 cases there was little or no effect, while in one case the patient became definitely worse, the basal metabolic rate and pulse rate rising from +32 per cent. and 100 to +53 per cent. and 128 respectively. Thus improvement followed the administration of iodine in 84 per cent. of cases. In mild cases with a basal metabolic rate of +20 to +25 per cent. the improvement which followed iodine administration was slight, and it was often difficult to say whether it was the relaxation from mental worry or the iodine which caused the improvement.

In 16 cases the effects of a second course of iodine were observed; these include 11 cases from the first group, on whom the results of a first course of iodine have already been noted. The interval which elapsed between the first and the second course in these 16 cases was variable, and appeared to influence the subsequent action of the drug—the longer the interval the more likely is it that the drug will act a second time; but this is by no means invariable. The length of time that the drug was continued on the first occasion also seems to be important; the longer the course the longer the interval before the drug will act a second time. If the course is a short one there is every likelihood of the drug acting a second time.

The lowest basal metabolic rate among these 16 cases was +33 per cent., while the highest was +75 per cent. In 6 cases the basal metabolic rate and pulse fell considerably at the end of ten days, and the improvement was quite comparable to the result of a first administration of iodine. In 5 cases the improvement was slight, but poor compared to the results of a first course. Three patients died within a month; they were very ill, however, when the iodine was given, and it is not thought that it hastened their deaths. In 2 cases the patients became definitely worse, the basal metabolic rate rising and the weight falling, but in one of these iodine had been of little value at its administration.

TABLE I.—*Results on the Basal Metabolic Rate of a Second Course of Iodine.*

No.	First Course.		Interval.	Second Course.	
	Before.	After.		Before.	After.
1	Per cent. +60	Per cent. +29	5 months	Per cent. +39	Per cent. +13
2	—	—	4 months	+35	+15
3	+46	+27	10 weeks	+53	+14
4	+60	+19	7 months	+59	+15
5	+71	+41	3 weeks	+75	+47
6	+59	+13	3 weeks	+61	+31
7	+70	+28	3 weeks	+39	+26
8	—	—	1 year	+53	+44
9	+114	+56	6 weeks	+75	+65
10	+65	+31	4 weeks	+50	+40
11	—	—	1 year	+33	+26
12	+72	+42	9 months	+70	Died
13	—	—	6 months	+54	Died
14	+60	+40	1 month	+72	Died
15	—	—	1½ years	+55	+70
16	+52	+48	3 weeks	+54	+61

From these figures it is seen that in only 37 per cent. of cases was a second course equal to a first. In all cases in which improvement was noted the maximum fall in the basal metabolic rate and pulse rate occurred in ten to fourteen days: in only one instance did the basal metabolic rate fall to any marked extent after the fourteenth day.

Cowell and Mellanby,[6] using small doses of potassium iodide, noted that the fall of the basal metabolic rate occurred in ten to twenty days, while Cole[7] says it occurs in two to three weeks.

It has been shown by most writers that improvement is merely temporary, that eventually there is a gradual exacerbation of symptoms with a coincident rise in the basal metabolic rate and pulse rate, and that this period of improvement depends largely, if not entirely, on whether the patient is exposed to worry or not. If the patient is kept away from the anxieties which attend home life or is treated in an institution, the basal metabolic rate may begin to rise again after two weeks and then gradually increase in height until it reaches the level prior to the administration of iodine. On the other hand, in some patients it may show no tendency to increase for four or five weeks, and in others eight weeks may elapse without any rise, but as soon as such a patient is sent home from hospital the basal metabolic rate returns to the original height.

I will quote three cases to illustrate these points and to emphasize that relapse ensues as soon as the patient begins to worry or is sent home.

1. A married woman, aged 30, was admitted to hospital; after she had rested in bed for a week the basal metabolic rate was +72 per cent. and the pulse usually about 120. She was given Lugol's iodine, and ten days later the basal metabolic rate was +28 per cent. and the pulse 92. Fourteen days later a rise to +45 per cent. was noted, while when a further nineteen days had elapsed it had risen to +57 per cent. and the pulse was then about 110.

2. A patient was given Lugol's iodine, and the basal metabolic rate fell to normal. It remained within normal limits for three weeks, at which time she received news that her child was not well. The basal metabolic rate rose the next week to +57 per cent., and consideration for her health forced us to send her home.

3. A patient was admitted to hospital, and after seven days' rest in bed the basal metabolic rate was +70 per cent. and the pulse 115. She was given Lugol's iodine, and ten days later the basal metabolic rate was +47 per cent. and the pulse 100. The basal metabolic rate varied between +44 and +53 per cent. for seven weeks, and she was then sent home, iodine treatment still continuing. Five weeks later she was readmitted, and the basal metabolic rate was +75 per cent. and the pulse 130.

If a patient has been given iodine and the basal metabolic rate and pulse rate have been lowered, the stopping of the iodine is followed by an immediate relapse. If the basal metabolic rate and pulse have been lowered, and after perhaps five weeks have risen slightly, but not to anything like the previous height, the withdrawal of the iodine still results in a relapse. In both cases the basal metabolic rate rises to the original level before iodine was given. On the other hand, in cases where iodine has been given, and the basal metabolic rate and pulse have gradually relapsed to their levels before iodine was administered, stopping the drug now appears to have no effect whatever; further, the patient does not appear to improve as the result of stopping the drug. I have frequently ceased to give a patient iodine after she has been on it continuously for six months, and the basal metabolic rate and pulse have not been influenced for better or for worse. On the other hand, Fraser[8] considers that 6 minims of 10 per cent. tincture of iodine may do harm if continued over a long period. Several French physicians, however, give larger doses than is customary in this country over a longer period, and claim that they obtain better results.

As shown above, in only 6 out of 16 cases was the response to a second course of iodine satisfactory. This means that in 10 cases, were an operation contemplated, the patient would not be able to have the beneficial effect of iodine as a preparation for the operation.

An example of this is that of a girl, aged 19, who was admitted to hospital with a basal metabolic rate of +59 per cent. and a pulse of 120. She was given Lugol's iodine, and ten days later the basal metabolic rate was +13 per cent. and the pulse 84. She refused operation and went home, but ten weeks later she was readmitted with a basal metabolic rate of +65 per cent. and a pulse of 125. During seven of these ten weeks she had been having iodine. On admission, Lugol's iodine, 10 minims three times a day, was prescribed, but the basal metabolic rate and pulse never fell below +60 per cent. and 120 respectively; the dose was then increased further, and the basal metabolic rate fell to +31 per cent., but no further.

The seriousness of such a state of affairs was emphasized by Goetsch.[2] In such a case, if an operation is undertaken, the risk is considerable, while had operation been performed when the patient was first given iodine the risk would have been far less. As it is held by most authorities that iodine by itself cannot cure exophthalmic goitre it seems only fair to the patient that iodine should be held back until an operation is decided upon, since its value in preparing patients for operation is well recognized, and is reflected in the improved mortality rates in published cases.

Iodine is an excellent remedy for the crisis with vomiting with which many patients are troubled, but if a course has already been given its value at such a time may be disappointing. On five occasions I have seen cases where a course of iodine has been given for months and then stopped. Later, the patient has had a crisis with vomiting, and iodine was valueless in checking it. More often than not, however, the crisis can be controlled by giving iodine, whether the patient has had it before or not.

In prescribing iodine I have rarely given a larger dose than 30 minims of Lugol's iodine a day, as it is said that large doses cause an actual exacerbation of symptoms. Cowell and Mellanby[6] found that improvement followed minute doses of potassium iodide, such as 2 or 3 grains a day, and they do not think that large doses are necessary. After the maximum reductions in the basal metabolic rate and pulse rate have been apparently reached an increase in the amount of iodine reduced the basal metabolic rate and pulse rate still further in 3 cases. These patients had had iodine for several weeks; in 2 cases the basal metabolic rate and pulse rate had returned to the levels before iodine was given, while in one case, already mentioned, it had had little or no effect. It was decided to operate on them, and the dose of Lugol's iodine was increased from 20 minims a day up to 40 minims. In the first case the basal metabolic rate fell from +65 to +31 per cent., in the second case from +34 per cent. to within normal limits, and in the third from +75 to +40 per cent. The first two patients were operated upon at once, but in the third the mistake was made of increasing the dose to 50 minims, and in spite of this, or because of it, the basal metabolic rate rose within a week to +63 per cent.

A striking fact which is noticed during iodine administration is the patient's increase in weight. This increase

* Insisted on operative treatment. † Refused further treatment. ‡ Operation considered advisable.

will often continue when the basal metabolic rate and pulse rate are rising. Thus, a patient weighing 5 st. 7 lb. was admitted with a basal metabolic rate of +70 per cent.; she was given iodine, and ten days later the basal metabolic rate was +28 per cent. and the weight was 5 st. 12 lb. Six weeks later the basal metabolic rate was +57 per cent., but the weight had increased to 7 st. 3 lb.—an increase of 19 lb. while the basal metabolic rate was rising from +28 to +57 per cent.

TREATMENT BY X RAYS.

The treatment by *x* rays is probably the most widely adopted to-day, and its chief merit lies in the fact that there is no mortality rate, although patients may die during the course of treatment as the result of the disease itself. *X*-ray burns, which a few years ago were only too common, are now rarely seen, and, indeed, the only cases seen recently are of patients who received treatment some years ago. It is probably no more frequent than injury to the recurrent laryngeal nerve during thyroidectomy.

The question whether *x*-ray therapy is of any value was discussed at the British Medical Association Meeting at Edinburgh in 1927, and most of the speakers were rather sceptical. Walton[10] recently said he did not think it was of much value, but there are many who have great faith in it, and some who make extravagant claims for its value. Little has been published in this country on *x*-ray therapy, but Hayes[11] found there was improvement in 76 out of 100 patients treated by him. Unfortunately no basal metabolic rates were given, and one has to rely on his judgement. Sanger[12] obtained good results in 41 out of 50 cases, and his results are adequately supported by basal metabolic rate estimations on all the patients. Borak[13] stated that 80 per cent. of patients improve, while 33 per cent. become free of symptoms.

There can be little doubt, therefore, that *x*-ray therapy is a valuable line of treatment in some cases. The time required to produce results is doubtful; some say one to four months, while Murray[14] states that it may take as long as two years.

I have been able to collect 23 cases in which I had examined the patients before the commencement of *x*-ray therapy, repeatedly during the course of treatment, and, finally, at the end of a year or at the termination of their treatment. Since it is undoubtedly a fact that various factors, such as excitement, influence the basal metabolic rate, great care has been taken in arriving at an accurate result, and in my cases the basal metabolic rate given is the mean of several estimations.

All the patients had well-marked signs and symptoms of exophthalmic goitre, and it will be seen that no patient had a basal metabolic rate of less than +30 per cent. at the commencement of treatment. A number of other patients were treated, but they would not come into hospital for a basal metabolic rate estimation, and so are not included. Some very mild cases with basal metabolic rates of around +20 per cent. were also treated, but in many of these it was not considered absolutely certain that they were not simple cases of neurasthenia.

The actual method of treatment is as follows:

Coil and Coolidge tube. Kilovoltage 80. Current 3 milliamperes. Filter 3 mm. aluminium *plus* two layers of felt. Dosage measured with Sabouraud pastilles, and a dose equal to half tint B (with filter in place) is given. This equals with apparatus in use a quarter of an erythema dose. Treatments are given at first twice a week, then once a week, and the intervals are gradually lengthened until a total of about thirty doses has been given, spread over a year. The interval between the doses and the total number of doses given depends on the progress of the patient.

In Table II, showing *x*-ray results, the details are given in the following order: (1) basal metabolic rate, (2) pulse rate, (3) weight in pounds.

In 6 of these 23 cases it will be seen that the basal metabolic rate has returned to within normal limits, and the pulse rate is between 70 and 85 beats per minute. The weight has increased in each case, the smallest increase

being 5 lb. and the biggest being 20 lb., while the average increase is 11 lb. In 6 cases there has been improvement, and in 5 of these the improvement was marked. The basal metabolic rate has fallen considerably in each instance, but not to within normal limits, while there has been an average increase in weight of 6 lb.

In 9 cases there was no improvement worth recording; in 5 of these the patients were emphatic that they felt no better, and either clamoured for an operation or refused further treatment. The other 4 cases showed no improvement whatever. Records for one year's treatment are given, while actually they have been treated for sixteen months and no improvement has been noted; it is not thought there is any likelihood of further change. Two deaths occurred, and it will be seen that one patient died after being treated for ten months and the other after receiving treatment for twelve months.

The time required for cure or improvement has now to be considered. It will be seen that among the cured cases the average duration of treatment necessary to bring the basal metabolic rate and pulse within normal limits is six and a half months, but it may occur as early as at the end of two months or as late as twelve months.

Among the cases classified as improved, the improvement was obvious in most cases by the third month, and in all cases by the sixth month. It seems fair, therefore, to assume that if benefit is likely to be derived from *x* rays, improvement will be noted in six months, whereas if there is no amelioration of symptoms during this period it is doubtful if further *x*-ray therapy will be of much value. The cases which responded most satisfactorily to *x*-ray therapy were those in which the signs and symptoms were of short duration, the size of the goitre being of less importance. Cases of longer duration in which the goitre was moderately enlarged and firm often improved, but were very seldom cured. The longer the disease has existed the less hope is there of benefit being derived from *x*-ray therapy.

Operative Treatment.

The third line of treatment is surgical: before giving the results it is desirable to describe briefly the procedure in each case. The patient was put to bed, and after she had rested for three days the basal metabolic rate was estimated; this was repeated until a consistent result was obtained, since frequently the second estimation is lower than the first, but the third is usually the same as the second. This is because on the first occasion the apparatus is apt to frighten the patient, and this in itself is sufficient to give an inaccurate result.

The patient was next given Lugol's iodine, 10 minims three times a day, and at the end of ten days one or more basal metabolic rate estimations were made; the patient had an electro-cardiograph taken, particular attention being paid to the inversion of T in lead II, and less attention paid to an inversion in lead III. If the basal metabolic rate was +30 per cent. or under, the pulse rate under 95, and the electro-cardiograph gave no contraindication, the case was regarded as operable. More attention was paid to the basal metabolic rate than to the pulse or electro-cardiograph, though all three received attention. There was no undue haste in operating, as it was felt that nothing was lost by waiting up to three weeks, while the increased weight at the end of that period, and the fact that patients often felt better after three weeks than after two weeks, convinced me that something was to be gained by a short delay. After the operation, which was a complete one wherever the basal metabolic rate was under +30 per cent., iodine was continued for three days. It will be seen that some patients were operated on whose basal metabolic rate was higher than +30 per cent. In these patients medical treatment had been given a complete trial, and in each case it was felt that unless an operation was performed the patient was likely to be an invalid until an early death.

I have been able to collect 25 consecutive cases in which the basal metabolic rate was estimated before and after operation, and the fact that no deaths occurred was very gratifying. The object in giving a list of these cases is not only to emphasize the fact that care and discrimination can reduce the mortality rate, as the Mayo Clinic have done this, but, first, to compare the immediate results with the results after a year or longer, and, secondly, to compare these results with those of *x*-ray therapy. Since the introduction of basal metabolic rate estimations there have been no deaths in this hospital, and this contrasts strongly with a mortality rate of 15 per cent. in the 25 cases preceding.

TABLE III.—*Immediate Results of Operative Treatment.*

No.	Before Iodine.		After Iodine		After Operation.		Operation.
	B.M.R.	Pulse.	B.M.R.	Pulse.	B.M.R.	Pulse.	
	Per cent.		Per cent.		Per cent.		
1	+53	113	+33	93	− 9	79	Thyroidectomy.
2	+40	110	+23	90	+39	95	Thyroidectomy.
3	+34	96	+ 6	80	− 5	84	Thyroidectomy.
4	+61	110	+13	90	0	84	Thyroidectomy.
5	+38	91	+30	83	+ 8	80	Thyroidectomy.
6	+89	132	+53	130	+44	100	Lobectomy.
7	+64	110	+33	102	− 4	80	Thyroidectomy.
8	—	—	+15	85	−15	76	Thyroidectomy.
9	—	—	+14	90	− 7	72	Thyroidectomy
10	+111	135	+56	103	+39	95	Ligation.
11	+78	125	+65	115	+32	124	Sympathectomy.
12	+25	100	+27	95	0	76	Thyroidectomy.
13	—	—	+23	93	+ 5	84	Thyroidectomy.
14	+57	104	+26	83	+20	85	Thyroidectomy.
15	+60	116	+24	95	−10	70	Thyroidectomy.
16	+43	110	+14	90	+13	85	Thyroidectomy.
17	+57	116	+13	90	− 8	76	Thyroidectomy.
18	+65	112	+31	100	+17	84	Thyroidectomy.
19	+53	104	+14	84	− 3	80	Thyroidectomy.
20	+57	116	+18	90	− 8	80	Thyroidectomy.
21	+51	110	+26	96	+10	72	Thyroidectomy.
22	+39	96	+26	80	+13	70	Thyroidectomy.
23	+80	120	+40	100	+63	100	Lobectomy.
24	+38	100	+16	85	−11	80	Thyroidectomy.
25	+53	110	+12	85	0	75	Thyroidectomy.

The ligation and sympathectomy were performed on the same patient, and there can be no doubt that the patient was benefited by these operations. A basal metabolic rate estimation was made a year after the sympathectomy; the result was +26 per cent., and the pulse was 90. Of the remaining 23 patients 17 have been cured by the operation, while in 6 cases the basal metabolic rate is still above normal limits; 4 of these have been considerably improved by the operation, and indeed it was a surprise to find in 3 of them that the basal metabolic rate still persisted above normal limits. The remaining two patients were not relieved of their symptoms and signs, and I felt, entirely apart from the basal metabolic rate, that the patients were not benefited to any great extent. It is obvious that in order to justify any surgical procedure the results must be considerably better than non-surgical methods, and, comparing the surgical results given here with the *x*-ray results, I feel that the surgeon has proved his case. The figures published by surgeons never give the number of cases regarded as inoperable and sent for medical or *x*-ray therapy. While the average case treated by a radiologist is more severe than that treated by a surgeon, it must be admitted that in operable cases the results are excellent—so good that it might be better for patients if experienced surgeons temporarily forgot mortality rates and did their fair share in the treatment of the disease.

The next step was to examine patients who had been operated on a year or longer, and to compare these results with the immediate results of operation, and also with cases treated by *x*-ray therapy. It is always difficult to get patients who have been treated a year or longer to return for a couple of days to hospital in order to have a test made,

but 16 patients did so, and, as in previous examinations, the basal metabolic rate was estimated and a careful four-hourly pulse chart kept. The basal metabolic rate and the mean pulse collected from the charts show that these results are pleasing, but not quite so convincing as the immediate results. Four cases in which one lobe was removed are given, and in each the basal metabolic rate has remained above normal limits.

TABLE IV.

No.	Years since Operation.	B.M.R.	Pulse.	Operation.
		Per cent.		
1	1½	+ 3	80	Thyroidectomy.
2	2½	+40	99	Lobectomy.
3	1½	+10	80	Thyroidectomy.
4	1	+ 7	83	Thyroidectomy.
5	1½	+19	95	Thyroidectomy.
6	1	+25	95	Lobectomy.
7	5½	+ 8	70	Thyroidectomy.
8	2½	−12	80	Thyroidectomy.
9	1	+40	100	Lobectomy.
10	1	+15	84	Thyroidectomy.
11	1	+10	84	Thyroidectomy.
12	1	+12	80	Thyroidectomy.
13	1	+ 5	60	Thyroidectomy.
14	1	+27	90	Thyroidectomy.
15	1	+14	85	Thyroidectomy.
16	2	+60	95	Lobectomy.

In the cases shown it would appear that about 80 per cent. of patients operated on are cured or are considerably benefited by thyroidectomy, and these figures hold good for at least one year after operation. The best result that has been obtained from *x*-ray therapy is improvement or cure in 12 out of 23 cases—that is, 52 per cent.; if the surgeon's mortality rate is not above the average the difference of 28 per cent. between the surgical and the *x*-ray results certainly seems to justify surgery and to give it the premier place in the treatment of the disease. Many surgeons who do not operate frequently on exophthalmic goitres have a rather appalling mortality rate, and whereas one may advocate surgery for some cases, it cannot be too strongly emphasized that surgical intervention should only be undertaken by an experienced surgeon. In few diseases will care and discrimination in the preparation and selection of the cases be rewarded by more gratifying results.

There are many patients with Graves's disease who are improved or cured by *x*-ray therapy; in view of this it seems only fair that the radiologist should be given a chance before the case is sent to a surgeon. The patient ought to be treated for about six months by *x*-ray therapy, and if at the end of that time the basal metabolic rate, weight, and pulse have not improved, it is probably useless to continue.

SUMMARY.

An attempt is made to compare the results of treatment by medical measures, *x*-ray therapy, and operative procedures. Any improvement or failure to improve is supported by the basal metabolic rate, the pulse, and in many cases the weight.

I am able to support the view held by many that iodine causes only a temporary amelioration of symptoms and signs, and that prolonged iodine treatment is of no benefit to the patient. The stopping of iodine after it has been given for some months did not cause any change in the patient's condition, as judged by the basal metabolic rate and pulse. A second course of the drug does not give the uniformly good results of a first.

X-ray therapy is considered; it is found that in only 52 per cent. of cases does any material improvement result, and improvement will be obvious in six months from the start of treatment. Cases in which there is no improvement after six months of treatment should be referred to a surgeon for operative procedures.

Operative treatment is dealt with, and a list of cases is given showing the basal metabolic rate and pulse before and after operation; it is found that over 80 per cent. are cured or improved. Emphasis is laid on the fact that usually only patients in whom the basal metabolic rate was under + 30 per cent. and the pulse under 95 after iodine therapy were operated on. A second list is given showing the basal metabolic rate and pulse a year or longer after operation, and it is found that about 80 per cent. maintain their improvement. The fact is stressed that the most unsuccessful cases are those in which too little of the goitre is removed.

In conclusion, it is considered that iodine should be reserved until it is considered necessary to operate; that the patient should be given a six months' trial with *x*-ray therapy; then, if improvement does not occur, or if it is not reassuring, the patient should be sent to an experienced surgeon for operation if suitable.

I wish to thank the physicians, surgeons, and radiologists who allowed me to carry out these investigations on their patients.

A NOTE ON NARCOLEPSY.

WITH REPORT OF A CASE.

BY

A. M. KENNEDY, M.D., M.R.C.P.,

PROFESSOR OF MEDICINE, UNIVERSITY OF WALES.

THIS curious condition is characterized by paroxysmal attacks of sleep, frequently coming on during the day and often quite irresistible. Gélineau[1] apparently first described the condition in 1880, and very few cases had been recorded when, in 1923, Worster-Drought[2] directed attention to the subject by reading a paper before the Medical Section of the British Psychological Society, giving an account of three cases which had been under his care. Last year Kinnier Wilson[3] summarized the current knowledge of the various forms of narcolepsy and collected records of 43 cases from the literature. At the beginning of the present year (1929) Fulton and Bailey,[4] writing from the surgical clinic of Dr. Harvey Cushing, published an interesting contribution to the study of tumours in the region of the third ventricle, and discussed their diagnosis and relation to pathological sleep.

Attacks of sleep may, of course, be symptomatic of other definite pathological lesions, such as cerebral arteriosclerosis, dyspituitarism, suprasellar cysts, encephalitis lethargica, etc., but there is a group of cases which would appear to be "idiopathic" or "functional" in so far as no underlying organic disease has been discovered. Some of these "idiopathic" cases may have cataplectic attacks associated with the narcoleptic.

The patient whose case is now recorded was a motor car driver, who first came under my care about the beginning of November, 1928. He was then 26 years of age, and the narcolepsy was well marked. Symptoms had commenced about thirteen months previously, but it was not until four months after coming under observation that cataplectic attacks set in.

His sister, when about 23 years of age, had a "nervous breakdown," and was unable to follow her occupation as a clerk for about two years. During this period she had a constant feeling of fullness in her head, and was subject to attacks of hysteria, depression, and crying, but never had any sleepy attacks. In his own personal history there was nothing of note until he reached the age of 15 or 16 years, when he was off work for three months with a bad attack of "influenza." He seemed to have had no serious effects or sequelae of this illness, except that for some time after he suffered from "blueness" of the hands, suggesting to his doctor at that time a mild Raynaud phenomenon. Eventually, however, this condition disappeared, but later he began to have occasional "flushings" of the face, and these have troubled him from time to time since.

At the age of 22 he began to have occasional transient attacks of double vision, lasting five to ten minutes. At first, and for

a long time, he would only have an attack about once a month, but eventually they became a little more frequent. It was his custom during such an attack to close one eye so that he could drive straight. About three years later, when about 25 years of age, he began to suffer from a feeling of fullness and throbbing in the head, and it was just about this time that he first began to be troubled with attacks of drowsiness—a tendency to fall asleep—while driving the motor car. These sleepy attacks came on quite suddenly; he had no "aura" or warning, and although he never actually fell asleep while driving it was only by a very great effort of will that he was able to ward the sleep off. Usually he just dozed for a few seconds, and then his employer, sitting beside him, would rouse him by a nudge or shout, telling him to mind where he was going, as he would be driving zigzag. He had many a "narrow squeak." Sometimes when he felt an attack coming on he would make an excuse to his employer to stop the car, jump out, and look at the engine, as he found that by this manœuvre he could get a chance of waking up and so warding off the attack.

Occasionally, when an attack was threatening, his driving would be so erratic that he slowed down for a short time till he could ward it off. He always felt that if he did not "pull himself together" he would have gone right off to sleep. Sometimes, when he had to wait outside a shop for his employer, he would fall asleep completely, and once or twice he has fallen asleep while smoking, and the cigarette has dropped from his mouth and burned him.

The attacks at the outset always occurred when he was engaged driving the motor car, and naturally caused him great and constant anxiety. He carried on for another six months in spite of almost daily attacks, until one day he dozed off and nearly crashed into another car. He then realized that he would have to give up his occupation. That night, while shaving, and for no apparent reason, he "seemed to lose control of himself" and threw his razor and brush across the room. A few days later he was admitted into hospital under my care.

He appeared to be a bright, active man, and weighed 9 st. 9½ lb. He had rather an anxious expression, and was easily startled, any slight stimulus—for example, a noise—causing his limbs, body, or head to jerk spasmodically. On inquiry he stated that these spasmodic movements had only affected him since the day he gave up work (that is, the day he nearly crashed with his car), and that they frequently occurred at night just as he was dropping off to sleep—particularly if the room was dark or his eyes were covered up by the bedclothes. His reflexes were all very active, but, apart from this, physical examination failed to reveal any abnormality. The fundi of the eyes and fields of vision were normal, and the ears and throat showed nothing of note. On *x*-ray examination of the skull a few faint opacities suggesting lime salts were seen at the site of the pineal gland, but no abnormality of the sella turcica was made out. He had no vomiting, no adiposity, no abnormal thirst; the urinary output was normal, and examination of the urine revealed nothing of note. His Wassermann reaction was negative, blood sugar normal, and systolic blood pressure 133 mm. of mercury.

When in the ward he slept soundly at night, and frequently dropped off to sleep during the day if the ward was quiet. He often shouted out in his sleep, and at times he would have sudden and fairly violent spasmodic movements of his limbs, body, or head when any unusual noise occurred. He had occasional flushings of his face, and he began to complain of his forehead feeling hot. His forehead undoubtedly felt hot to the touch, and this curious phenomenon has persisted. Throughout his residence in hospital he complained of a feeling of fullness in his head, and at times he had definite headache. He had been much troubled with dreams since a month or two before coming into hospital, and after coming in never slept without dreaming—whether by day or night—and occasionally he had definite "night terrors," which woke him up. Notwithstanding having wakened up in a bad dream he would go off to sleep again quite easily.

During the seven weeks he was under observation in hospital he became less easily "startled," the sleepy attacks became less frequent and he felt less "tired," and before he left the spasmodic jerkings had practically ceased. After leaving he went for a week's holiday, and was decidedly better then. He ascribed the improvement to the fact that he was among strangers, for he felt that he was then better able to control himself.

On returning to his own home the sleepiness recurred as bad as ever. Going to bed at 10:30 p.m. he would sleep till awakened for breakfast about 9.30 a.m., and after having breakfast he would sleep again until roused about midday or he woke of his own accord. When out in the afternoon he always felt that he wanted to drop off to sleep. He would, however, fight against it by keeping on walking, or if somebody accompanied him and kept him occupied by talking the drowsiness was not so troublesome.

About two months after leaving hospital he had his first cataplectic attack.

One afternoon while crossing a busy street, accompanied by his wife, he saw some cars coming towards him, when, suddenly, he became quite limp and unable to move. He had to be supported by his wife, otherwise he might have collapsed to the ground. During this attack, which lasted two or three minutes, he was quite conscious and could see the traffic going round and past him. His wife with difficulty managed to get him across to the pavement, where, after a few minutes, he felt better and was able to walk home. He was weak and rather limp for the remainder of that day. Three days later he had another similar attack.

The spasmodic jerkings returned after the first cataplectic attack, but they and the cataplectic attacks became less troublesome, and about two months later had almost passed off. He was then less drowsy, and felt he had more control of himself, although rather "weak about the knees," and occasionally he would have transient double vision.

His condition has remained much about the same—at times rather better, at other times rather worse. He says that if he worries about himself—for example, about not getting better—he is worse, starts to shake, and gets "jumpy turns." When he does not think about himself he is better. His sleep is just like ordinary sleep, but he never feels properly refreshed afterwards, and always has the feeling of fullness in his head. He sometimes has attacks of continuous yawning, and he thinks that if he "let himself go" he would sleep continuously.

It is now twenty months since the onset of his symptoms, and he has never shown any of the ordinary signs of intracranial tumour. At first the periodic diurnal drowsy attacks—narcoleptic—occurred alone, but later cataplectic seizures were superadded to the clinical picture, and tended to confirm the opinion that the case should be included in the "idiopathic" group of the narcolepsies.

One point only in the previous history is worthy of further mention. He had had an attack of what he called "influenza" when 15 or 16 years of age, and in consequence was off work for three months. There is always the possibility that this might have been encephalitic in nature, but of this one cannot be sure. It was, however, six years later before he began to have occasional and transient attacks of diplopia, and a further three years elapsed before his narcoleptic symptoms began.

A NOTE ON A COMPARATIVELY RARE DISPLACEMENT OF THE INTERNAL EPICONDYLE OF THE HUMERUS.

BY

E. STANLEY BRENTNALL, M.B., F.R.C.S.Ed.,

HONORARY ORTHOPAEDIC SURGEON, STOCKPORT INFIRMARY; ORTHOPAEDIC SURGEON, CRUMPSALL INFIRMARY, MANCHESTER; HONORARY ORTHOPAEDIC REGISTRAR, ANCOATS HOSPITAL, MANCHESTER.

In February, 1928, I operated on a boy of 15, who, as the result of a fall on his hand, had, without any dislocation, driven his internal epicondyle within his elbow-joint. At no time was there any ulnar nerve block. The fragment was withdrawn from the joint and removed. The attached soft parts were used to close the gaping defect in the capsule. Within two months recovery was complete, except for an almost negligible loss of extension that disappeared quickly after his discharge from treatment. Normal appearance and function were regained. *X*-ray outline drawings are shown (Figs. 1 and 2).

It seemed at this time that the lesion was a very rare one, as references to it in medical literature were difficult to find. Since then, however, two papers have appeared which describe the condition, and in one of these the author claims twelve cases. Early this year I met a second case precisely similar to the one briefly described, and

I am now driven to the conclusion that the injury, though seldom recorded, and unencountered by many surgeons of experience with whom I have spoken, is by no means as rare as was at first thought. For this reason it is perhaps not out of place to describe in detail the features of the latter case, together with the operative findings. In the light of the earlier experience gained the nature of the

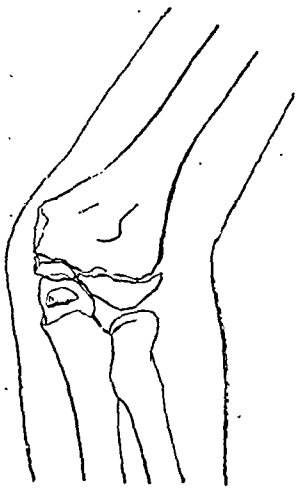

FIG. 1.

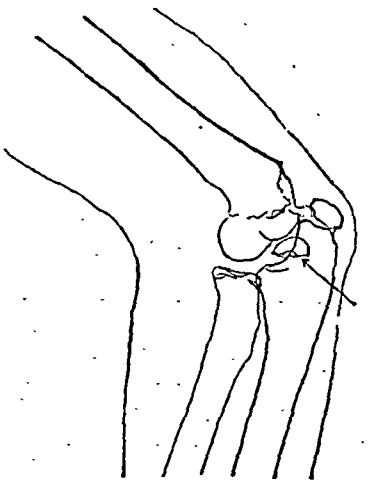

FIG. 2.

lesion was fully realized, and Miss Greg, M.R.C.S., kindly consented to make the sketches of the various stages of the operation which are shown here.

A girl, aged 13, some three or four days before she was seen, had fallen on her forearm, which was pronated and held in front of her. There had been no dislocation. Bruising extended widely over the front and inner aspects of the elbow and its vicinity. Flexion and extension movements were much lessened, but a small intermediate range, surprisingly free and painless, still existed. Tenderness was greatest over the inner side of the lower end of the humerus. The inner condyle was less defined than the outer. No nerve lesion was present. An *x*-ray photograph (Figs. 3 and 4) shows a loose fragment of bone, as Walker described it in his case (loc. cit.), of almost the size and

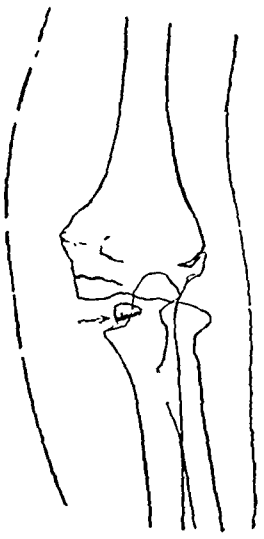

FIG. 3.

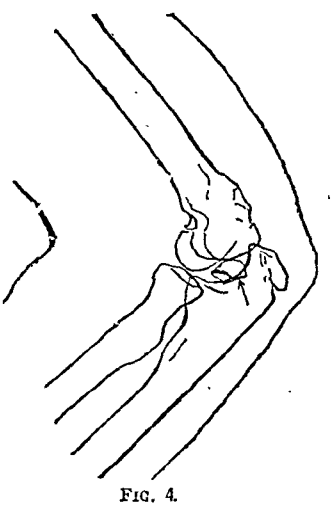

FIG. 4.

shape of a pisiform bone, lying between the widely separated articular surfaces of the humerus and ulna. There is a slight lateral subluxation of the forearm. Corroboration was given to the diagnosis by a skiagram of the normal elbow (Figs. 5 and 6).

The operative exposure was almost startlingly easy. Immediately below the skin, and as soon as its edges were retracted, the stump of the epicondyle, rough and sharply edged, came into view, leading directly downwards and forwards to the inner margin of the trochlear process. This part of the joint was divested entirely of its capsular covering. Just distal to the trochlea, and dipping abruptly into the interior of the joint, stretched a sheet composed of flexor origins and internal lateral ligament, which separated the humerus from the coronoid process of the ulna (Fig. 7). This was easily withdrawn, and brought with it the epicondyle attached (Fig. 8). At this point the amount of lateral play possible in the elbow was extreme. The forearm could be brought out easily to a

FIG. 5.

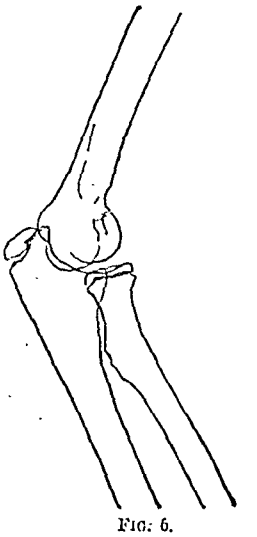

FIG. 6.

point of nearly 90 degrees of abduction. The fragment of bone was carried up and stitched to its bed, though, owing to the tension of the attached soft parts, not without difficulty. This exposure of the inner aspect of the humerus was so complete and easily made that the route commended itself as a formal operative approach when free access is desired for any purpose to the trochlea or the inner half of the elbow-joint cavity.

DIAGNOSIS.

Once the condition has been met and its anatomy seen no mistake will be made in the diagnosis when skiagrams in two planes are available. It is, however, doubtful whether the majority of those responsible for the treatment of such injuries would grasp its meaning when meeting it for the first time. My experience suggests that the skiagram does not evoke spontaneous or complete unanimity. No doubt some cases have passed for lesions of the coronoid process or the head of the radius, as in Cotton's patient (loc. cit.). The diagnosis is a pure skiagraphic one, and is to be made on (1) the presence of a small rounded nodule of bone between the gaping articular surfaces of humerus and ulna, and (2) the absence of the epicondyle from the humerus as seen from the front; this gives the internal condyle an abrupt and unfinished appearance. In an imperfectly

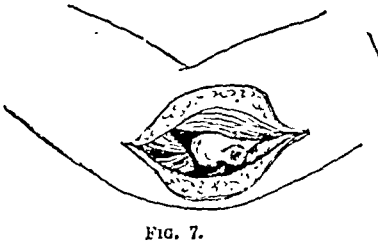

FIG. 7.

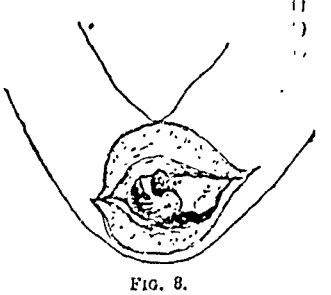

FIG. 8.

directed antero-posterior view this may not be obvious, but close inspection of the lateral skiagram will show the epicondylar base directed as usual somewhat backwards, but shortened, irregular, and jagged. A comparison with the normal side affords immediate help. The clinical examination of the patient does not suggest an injury of an unusual nature or one demanding operative intervention.

LITERATURE.

In 1924 H. A. T. Fairbank showed a skiagram of a similar case, and mentioned three others as examples of a very rare condition in which, as a result of a dislocation, the fractured epicondyle had entered the elbow-joint.

In April last year Walker published a well-illustrated and detailed account of a youth of 18 who dislocated his elbow laterally. The dislocation was reduced, but a subsequent *x*-ray photograph showed a typical fractured and misplaced epicondyle, together with a persisting lateral subluxation. There was an incomplete ulnar nerve lesion. The parts were restored by open operation, and a swollen contused ulnar nerve was noted at the back of the condyle.

This year Cotton records the last three of a series of ten completed cases met with during the last nineteen or twenty years. His first case was published nineteen years ago in his textbook. In addition, he mentions two others, more recent and not completed. Every one of these cases had an ulnar nerve lesion associated with the fracture, and gave a history of a dislocation treated before the patient was brought to his notice.

ETIOLOGY.

Fairbank, who speaks with great authority on epiphyses, associates the lesion always with dislocation, and makes the manipulative reduction responsible for the displacement of the epicondyle. It is unfortunate that the nature of the dislocations was not always noted in his account. Walker's case had a lateral dislocation followed by an incomplete reduction before he received it. Of Cotton's three described cases, each had a dislocation reduced before he saw them. Two of these are said to have been posterior; the third he found to be a still unreduced lateral subluxation. Cotton considers the lesion the result of manipulative reduction.

In the two cases here recorded no dislocation was known to have occurred, and certainly no manipulation. The cause, therefore, is not necessarily faulty reduction. In one the forearm was subluxated slightly outwards. So far as my histories are of value, it seems probable that the impact met the forearm held forward with the elbow bent: and, acting against a rigid internally rotated shoulder, caused a violent abduction strain at the elbow which tore away the epicondyle and caused the joint to gape. The amount of lateral mobility found at the operation showed that dislocation sideways would be a possible and even likely complication, and it is suggested that when dislocation occurs it is secondary to the tear of the inner part of the capsule. It is noteworthy that out of the four cases detailed (Walker and Cotton) lateral subluxations were found by the operator in two; the two others gave a history of a posterior displacement, but this had already been corrected.

A striking feature of Cotton's cases is the appearance without exception of the nerve block, which is unmentioned in Fairbank's. These were no doubt primary contusions resulting from stretching and friction over the sharp edges of the epicondylar bed at the moment of abduction, rather than compression due to the tension of soft parts, as Cotton seems to suggest. Not infrequently, as Platt has shown, nerve lesions are found in company with epicondylar separation, whether associated or not with dislocation, and these are possibly of similar origin. In the third case detailed by Cotton the nerve was actually found imprisoned between the humerus and ulna. To me this is capable of no other explanation than that wide abduction was produced with tremendous tension of the soft parts on the inner side of the elbow. The epicondyle and capsule giving way at this point, these structures entered the joint more or less in the same way as fascia, and even skin may be found nipped at the inner side of the knee after a severe abduction injury. The escape of the nerve in those cases in which no conduction block is evident is due presumably to an anatomical arrangement well behind the fracture or to the absence of highly energetic manipulations.

CONCLUSIONS.

It is possible that the injury described is distinctly commoner than might be supposed from its scarcity in the literature of elbow-joint lesions.

It is probably caused by a severe abduction strain, and is in the nature of an internal lateral ligament rupture. It is not uncommonly associated with a lateral subluxation of the forearm.

Detachment of the internal epicondyle with its lateral ligament and flexor origins is suggested as an operative approach to the inner side of the elbow-joint.

In conclusion, I must express my thanks to Miss Greg, who has been kind enough to make for me the sketches of the operation and the drawings of the *x*-ray appearances.

AGGLUTININS TO B. DYSENTERIAE IN THE APPARENTLY HEALTHY.

BY

J. MENTON, L.R.C.P. AND S.I.,

BACTERIOLOGIST TO THE COUNTY OF STAFFORD.

My reasons for undertaking the investigation of which details are given were as follows:

1. To obtain an estimate of the number of people now showing agglutinins to *B. dysenteriae* in the absence of a clinical history of the disease, and when the specimens are taken from patients residing in districts in which clinical dysentery is rare.
2. To examine the alleged influence of sex on the prevalence and strength of these reactions.
3. To ascertain the types of the dysentery group most frequently involved.
4. To determine to what extent the occurrence of these so-called normal agglutinins can interfere with the serological diagnosis of dysentery.
5. To compare the agglutinins in healthy people with those of a recent epidemic in order to see if there are any essential differences between them.

Many have investigated the subject, but there is a lack of uniformity in their findings, probably due to different methods of working, variable agglutinability of the cultures, or local epidemiological conditions. A great deal of work was done during the war, when the incidence of dysentery and the number of carriers were above the usual level. It seemed worth while to go into the question again under more settled conditions and with improved methods.

Professor Dreyer's technique was used; each serum was tested with standardized cultures of Shiga's bacillus; Flexner's bacillus, Types V, W, X, Y, and Z; and Sonne's bacillus. In addition to saline controls, each specimen was investigated with a standardized culture of *B. abortus* Bang, as this micro-organism was deemed a suitable contrast to the dysentery group. Positive results were verified at least once by different stocks of culture. Serums to the number of 524 were examined from 262 males and 262 females. The results are shown in the following table.

MALES.			FEMALES.		
No. of Specimens.	Types.	Units.	No. of Specimens.	Types.	Units.
2	Positive to Sonne	1	1	Positive to Sonne	6
5	" " "	2	6	" " V	2.5
1	" " "	6	6	" " V	4.5
1	" " V	4.6	3	" " V	11.5
3	" " V	11.5	1	" " Z	9
1	" " V	46			
1	" " W	13			
1	" " Z	10			
1	" " Y	4.5			
245	Negative to all		245	Negative to all	
262			262		

The total 524 serums showed 33 positive reactions—that is, 6.29 per cent. Most of these positive cases came from crowded industrial areas, and only a few from the rural

districts. The 262 males gave 16 positives, or 6.1 per cent., and the females 17 positives, or 6.48 per cent. The males reacted most frequently to Sonne's bacillus, and the females showed a predilection for Type V of the Flexner group. There were no agglutinins within the limits of dilution used to either the Shiga bacillus or Type X of the Flexner group, and the females failed to agglutinate the W or Y types. The serum giving the strongest reaction was from a male—46 units to Type V. There was no explanation of this high titre. The male showing 13 units to Type W was aged 21 years; he had not been inoculated, had not been abroad, and had never suffered from dysentery. All the positive reactors were questioned with a view to obtaining evidence of present or past disease, but in only one instance could a definite history of dysenteric infection be obtained. This man stated that he had suffered from severe dysentery thirty years previously and that he had lived in India for fifteen years. His reaction was 6 units to Sonne's bacillus; no dysentery bacilli were found in this patient's faeces. Four of the female reactors gave vague histories of periodic diarrhoea, and one woman, with 11.5 units to Type V, had suffered from recent diarrhoea of several months' duration. She stated that during the illness she had passed about seven motions daily, and that slime was present, but no blood. She was now quite well, but a specimen of faeces could not be obtained.

One female serum was positive to *B. abortus*, but no history of illness which could be associated with this micro-organism was obtained. The patient was negative to all the dysentery group. The result is mentioned in view of the recent publications pointing out the pathogenicity of this bacillus for human beings. Several of the positive serums to *B. dysenteriae* were re-examined over a period of four months, and in all except one the titre remained stationary.

A comparison between the results obtained in the above table and the serological findings in a recent small epidemic of dysentery showed that co-agglutinins were absent from the apparently normal series within the limits of dilution of the standardized test, but co-agglutination of closely associated types was common in the patients suffering from acute dysentery. In this epidemic, which was for the most part a Flexner V infection, the strength of the reactions varied from 4 to 114 units, and several specimens reacted in the neighbourhood of 11 units—that is, showed less agglutinins than several of the specimens taken from people showing no clinical evidence of dysentery. The proportion of positives in the epidemic on one test was only 40 per cent., and while this figure contrasts with 6.29 per cent. found in healthy people, it leaves a big residue of negatives.

COMMENT.

Many of the published estimates of the number of healthy people showing agglutinins are higher than on the present occasion. Major Manifold[1] in Poona has recently examined the blood serums of 66 British troops and 121 Indian troops who were not suffering from dysentery, or on the first or second day after the onset of dysentery before agglutination due to the existing attack could become apparent in the serums. He used Professor Dreyer's technique. Of the British 31.8 per cent., and of the Indians 50.6 per cent., were positive to the Flexner group. Flexner V agglutinins were present in a larger percentage and to a higher titre than the agglutinins of the other Flexner strains. The highest titre, 1 in 250, was observed in the Indian troops; the British troops in no instance showed agglutination in a higher dilution than 1 in 125. The high percentage found by this investigator is consistent with local conditions, as Flexner infection is frequent in Poona.

During the war other authorities[2] found agglutinins to the Flexner group in 91 out of a total of 120 recruits. The positive reactions were present in dilutions varying from 1 in 24 to 1 in 192. These results were obtained with Oxford Flexner cultures. No definite history of dysentery could be obtained from these soldiers, but four had recently suffered from diarrhoea and only three had been abroad. Dysentery convalescents and carriers were more frequent at the time of this investigation than they are now, and the high percentage of positives found may be reasonably attributed to subliminal infection resulting from the conditions of camp life at the time.

From the foregoing it will be realized that a patient suffering from dysentery may give a negative agglutination reaction, whereas a person without symptoms of disease may show agglutinins. This paradox is not so misleading as it appears to be, for in an epidemic a bacteriological examination of the faeces soon settles the matter, and, anyway, some of the patients suffering from acute infection may show strong agglutinins with a rapidly changing titre sufficient to give a useful lead when waiting for the isolation of the micro-organism. It is in the isolated case, or when the patient is suffering from mild and protracted diarrhoea, that difficulty arises, and then it is unwise to frame a diagnosis on the agglutination test alone unless the titre is convincing. The Medical Research Council have suggested a standard as indicative of active infection. Their report[3] states that 10 standard agglutinin units per cubic centimetre of serum in a man and 20 units in a woman are, for all practical purposes, diagnostic of an active bacillary dysenteric infection caused by the bacillus agglutinated, and that 6 to 8 units in a man and 12 to 16 units in a woman justify a strong suspicion of dysenteric infection, provided that the patient has not previously had the disease or has not been inoculated. This standard is a great help, especially in so far as it refers to the higher titres, which are definitely stated to be diagnostic, but it is not infallible, and active dysentery cases may not reach the required titre and apparently normal people may exceed it.

When considering the source of these so-called normal agglutinins it should be remembered that, though widespread serious Flexner epidemics are rare in this country among civilians leading an ordinary existence, there is every reason to believe that mild infections are commoner than is generally supposed. Even when patients show definite clinical signs the causal bacillus may be concealed and outgrown by streptococci and *B. coli*. Streptococci are often present in abnormal numbers in Flexner infection. This fallacy is encouraged by faulty technique. Very frequently mild diarrhoea is ignored by the patient and never comes to diagnosis, and further loopholes are left by irregular fermenting types and the various para-dysentery bacilli.

The ease with which dysentery may occur in institutions shows that the micro-organisms are ubiquitous and that they only need some contributory factor to produce typical disease. Shiga infections are rarer in this country than Flexner and associated types, and it seems to be more than a coincidence that agglutinins to Shiga's bacillus were absent from the blood serums of the healthy people under review. The evidence, then, that most of these so-called normal agglutinins are due to subliminal or mild infection may be summarized thus:

(*a*) Shiga infections are rare in this country; agglutinins to this micro-organism are also rare in healthy individuals.

(*b*) When dysentery infections were more frequent in this country the percentage of healthy people showing agglutination was higher than that revealed in the present series.

(*c*) In countries where dysentery is now frequent the percentage of healthy people showing agglutination is much higher than in England. These results have been obtained by up-to-date standard methods, and should be comparable with the present series.

(*d*) Mild attacks of diarrhoea are often ignored by the patient, and do not come under the observation of the physician.

(*e*) Most of the positives in this investigation were obtained from people residing in thickly populated industrial districts.

(*f*) Normal agglutination is absent at birth.

We have a parallel in diphtheria of virulent micro-organisms producing serological changes with transient or unrecognizable disease, and it is now generally admitted that the natural antitoxin found in a large proportion of the population is the outcome of "larval" infection with the diphtheria bacillus. A more lasting antitoxin is produced by this mild diphtheria than by one acute typical attack. Although antitoxin and agglutinins are two

different things, it may be that similar factors are at work in dysenteric infections, and may explain the absence of lasting agglutination in some acute cases and its persistence in those people who can give no history of dysentery.

CONCLUSIONS.

1. Agglutinins to *B. dysenteriae* were present in 6.29 per cent. of 524 serums taken from individuals only one of whom gave a history of dysentery, thirty years previously.

2. The series consisted of an equal number of males and females. The males showed 6.1 per cent. positive and the females 6.48 per cent. The highest titres were found in specimens from males.

3. The males reacted most frequently to Sonne's bacillus, but the highest titres were to Types V, W, and Z of the Flexner group. The females reacted most frequently to Type V Flexner.

4. The presence of these "normal agglutinins" may interfere with serological diagnosis, as they sometimes come within the range of the standards laid down as indicative of active infection; besides, in active infections agglutinins may not always reach these suggested standards.

5. There is sufficient evidence to suggest that these so-called normal agglutinins are the outcome of subliminal or mild infection with homologous or associated micro-organisms, and that the term "normal" when applied to this reaction is a misnomer, and should be avoided.

My thanks are due to Dr. F. M. Rowland of Lichfield for revising the manuscript.

A CASE OF CONJOINED TWINS.

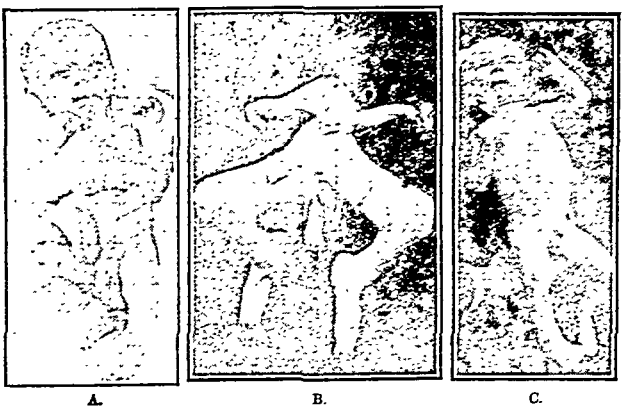
BY

M. WITKIN, M.B., CH.B., L.R.C.P. AND S.ED.,

DURBAN, SOUTH AFRICA.

RARE as are conjoined twins, still rarer are cases in which one twin is normal and the other has a parasitic foetus attached. The case recorded below seems, therefore, worthy of publication.

A multipara, aged 35, living near Durban, Natal, gave birth to male twins on November 12th, 1928. The labour was, on the whole, easy. The first child, a head presentation, was normal in every respect, and weighed 7 lb. The second child, a breech presentation, had a parasitic foetus attached to it. I was called half an hour after the delivery, as the midwife, finding an unusual bulging in the umbilical region of the second twin, was afraid to cut the cord. When I arrived I found the placenta in the bed, and after cutting the cord I noticed a hernia-like protrusion of the bowel in the umbilical area.



A. B. C.

A, The conjoined twins at the age of 2 months. B, The parasite immediately after the operation. C, The autosite at the age of 3½ months.

Family History.

The father is 38 years of age, a factory employee of poor physique, below the average height and weight, and of intemperate habits. The mother is a healthy woman, and is of average height, weight, and physique. Three other children (two boys and a girl), aged respectively 7, 5, and 3, are normal in every respect. There is no history of miscarriages or of difficult labour.

The Autosite.

The autosite, a small baby weighing 5 lb. 8 oz., was poorly covered, had deficient muscle tone, loose skin, a Hippocratic facies, and a feeble cry. It was alert, cyanotic, especially about the feet, and had normal powers of suction and deglutition. The head was normal, except that the cranial bones were unusually soft. The lungs, the upper and lower extremities, the abdomen, and the anal orifice were normally developed, and hearing, sight, and intelligence appeared to be normal. On the other hand, a bruit was heard in the heart, due, probably, to a patent foramen ovale, and the genito-urinary system was abnormal. The left testis was undescended, and micturition occurred at independent times from the penis of the autosite and from that of the parasite.

The Parasite.

The parasite was attached to the autosite by a pedicle the circumference of which was about that of half a crown. The pedicle was partly bony and partly muscular. The upper bony part was attached, slightly to the right, to the lower end of the sternum of the autosite; the lower part of the pedicle was muscular, and joined to the upper part of the abdominal wall.

The chest of the parasite was undeveloped, and contained no heart or lungs. Its upper extremities were rudimentary; the *right* arm was longer than the *left*, and each hand had one rudimentary metacarpal, finger, and nail. The lower extremities were well developed and equal in size, but they were flexed to a right angle, and could not be straightened or bent any further. The ankles were stiff; each foot had five well-developed toes. There were no testes in the scrotum, but the penis was well formed, and the parasite passed water over the autosite. There was no umbilicus and no anal orifice, though a distinct dimple marked the place of the latter. The parasite displayed no movement, but when its skin was pinched or pricked with a needle the autosite winced and uttered a feeble cry.

Operation for Umbilical Hernia.

On November 13th, when the child was one day old, I opened the abdomen, removed the hernial sac, returned the intestines to the abdomen, and closed the wound. The child made an uninterrupted recovery, the cyanosis disappearing almost at once and its general condition improving. Waterproof material was used to protect the wound from the parasite's urine. Healing took place by first intention, leaving a clean scar.

I considered that the child's condition did not justify an attempt to remove the parasite, and decided to wait a little before undertaking this operation. Later, however, when he was 10 weeks old, I found him looking *extremely ill*, and was able to induce the father to allow me to remove the parasite at once.

Removal of Parasite.

The operation was performed on February 6th under light chloroform anaesthesia. I made an incision round the pedicle, and on opening the abdomen I found that there was free communication between the abdominal cavities and between the bowels themselves. The peritoneum of the autosite was continuous with that of the parasite, but the latter's bowel had an independent mesentery attached to its posterior abdominal wall. The intestines of the parasite were very thin and narrow; they originated from the autosite's small intestine and ended in its lower bowel. The parasite had one small right kidney, but no liver or spleen. Large blood vessels and nerves passed from the autosite to the parasite. I ligated and cut the vessels passing into the parasite, and then decided to cut through the bowel of the parasite, taking care not to endanger the intestines of the host. Keeping as close to the parasite as possible, I clamped the bowel, removed it as one would an appendix, and returned the host's intestines into his abdomen. I closed the abdomen in the usual manner and brought the edges of the skin together by interrupted silkworm-gut sutures. The operation lasted fifteen minutes, and except for a little sloughing of the wound the child made an uneventful recovery. The parasite weighed 8 ounces.

The child was breast-fed at three-hourly intervals, and twelve hours after the operation he had a normal stool. The fact that thereafter the stools were of normal colour and consistency assured me that his intestines had not been damaged at the operation. He began to improve steadily and gained in weight, and a month after the operation he was still alive and doing well.

forms occurred between them and the latter. Barnard's view had now received pretty general acceptance, and it would appear that the vast majority of all mediastino-pulmonary growths were carcinomas derived from the bronchi, while sarcomas of the lymph glands or thymus were somewhat exceptional. The fact of the growths arising from a tissue which was exposed to agencies inhaled from without the body may have much significance for their causation. With regard to the distribution of the tumours and effects on local organs, 45 cases were examined post mortem during the past six years. In 13 of these there was a very large mediastinal growth, and in most of the remainder mediastinal glands were invaded. The lung roots were invaded in all except one case (right 23, left 18, both 3); the single exception was a lymphosarcoma in a youth of 17, the only one of the kind in this series. Bronchial involvement with ulceration and compression was definitely observed in 35 cases, and only noted to be absent in one, the lymphosarcoma. As a result of bronchial obstruction and infection there were abscesses or cavities in the lungs in 23 cases, and other effects in 9 more. The pleurae commonly showed effusions, sometimes haemorrhagic, and in 7 cases there was emphysema. Professor Shaw Dunn said that a very definite increase in the percentage incidence of these tumours among post-mortem cases was observed in Manchester by J. B. Duguid (1927), and analyses made at other centres in this country and abroad all agreed in showing an increased frequency, especially in the past ten years. The cause of this had not been discovered, but it had generally been assumed that prolonged inhalation of some foreign material from the atmosphere must be responsible. In this connexion the special liability of the Schneeberg miners in Saxony to cancer of the lung was of much significance. A possible causal factor for the disease in their case is arsenic, which is present in the dust of the mines. Any theory to account for the prevalence of lung cancer must accord with the fact of its much greater frequency in men than in women. The greater pulmonary ventilation occurring in heavy manual workers might play a part in this.

Radiological Aspects.

Dr. E. W. TWINING said that malignant tumours of lung and mediastinum gave rise to very diverse radiological appearances, which depended less upon primary histological character than upon the rate and mode of progression and on secondary effects—of which the most important were bronchial obstruction, atelectasis, infection, central necrosis with cavity formation, and pleural effusions and thickening. These factors might fundamentally alter the *x*-ray picture in a short time, and the progressive study of these changes in a series of cases had helped in the recognition of cases which came first under observation, as usually happened, with the disease well advanced. The differential diagnosis from tuberculous lesions, from encysted pleural effusions, and inflammatory lesions of the lung was not easy, and required very careful *x*-ray study; the full lateral view was essential, and the "hollow-back" position often useful. Judgement might have to be suspended, and the course of the case watched for a time. Special difficulty in diagnosis attached to the cavernous forms of growth, which simulate chronic abscess.

ACHLORHYDRIA AND PERNICIOUS ANAEMIA.

AT a meeting of the Section of Medicine of the Royal Society of Medicine on June 11th, with Dr. ARTHUR F. HURST in the chair, an address was delivered by Dr. W. B. CASTLE of Boston, U.S.A., on the result of some work carried out in Professor Minot's clinic on the relationship of achlorhydia to pernicious (or Addison's) anaemia.

Dr. Castle expressed the pleasure it gave him to speak on this subject in London, where the description of the disease originated, and where many of its features were first described. It was due to Hurst and other British physicians and investigators that research on the subject was started in America. The speaker believed that achlorhydria was almost invariably present in pernicious anaemia, that it preceded the development of the disease by a considerable interval, even years, and also that in the families of those who developed pernicious anaemia there would be found more than the average incidence of achlorhydria. It was interesting to note that other conditions which might lead to achlorhydria had also been followed by the development of pernicious anaemia. In extensive cancer of the stomach, achlorhydria and pernicious anaemia had been found to develop coincidently or subsequently. This was not always the case, but in some of these cancer cases he had seen the true blood picture and the reaction to liver extract. Certain cases of chronic alcoholism where gastritis had appeared and achlorhydria subsequently developed led in the same way to pernicious anaemia. Three cases were on record—one by Moynihan in this country, a second by Hartmann at the Mayo Clinic, and a third from Heidelberg—in which, after complete removal of the stomach, with, presumably, the production of complete achlorhydria, the patients, surviving the operation for at least a year, developed pernicious anaemia; there was no evidence in these cases of metastases or any other cause, such as bleeding, to explain the anaemia, and apparently in each of them the picture was complete. Dr. Castle mentioned an interesting case in New York. Here pernicious anaemia developed in a child aged 13, at which age the spontaneous appearance of the disease was very unusual. Liver extract was given, and the blood findings showed a characteristic response, but other symptoms, such as vomiting, continued, and, an obstruction at the pylorus being noted, an operation was done. It was found that at the pylorus a number of tuberculous lymph glands were matted together, almost occluding the opening. This, therefore, was a case of achlorhydria produced by obstruction at the pylorus, and producing in some way a picture of pernicious anaemia at an age when it was uncommon for the disease to develop.

The use of liver or liver extract had thrown the greatest light on this subject. When liver was given to a patient with pernicious anaemia he proceeded to develop a normal blood picture, and in every way became better, except perhaps for some residual nervous disturbance, but apparently there was no amelioration of the achlorhydria or achylia previously exhibited. The characteristic response to liver made one think of pernicious anaemia as a deficiency disease, though it was difficult from this point of view to understand why persons who never ate liver did not develop pernicious anaemia at once. It was true that, once having developed the disease, most patients had to continue taking liver or liver extract for the rest of their lives. But the speaker imagined it not difficult to think of a hypothesis which connected achlorhydria with the disease as a deficiency disease. Since liver was largely a protein substance, and the function of the normal stomach was obviously for the peptic digestion of protein, it was thought worth while to take the hypothesis that patients who had achlorhydria developed pernicious anaemia because they could not develop from the protein of ordinary food a certain necessary principle. Within a few days after the patient with pernicious anaemia had been given liver there appeared in the circulating blood a number of immature cells, recognized by the fact that they had a blue-staining network known as reticulum. For patients with less than 3,000,000 red blood cells per cubic millimetre it might be expected that with a maximum dose of liver or liver extract there would be an inverse relationship between the percentage of reticulocytes developed at the maximum point of the reaction and the red blood cell count. The speaker proceeded to describe some experiments, and showed tables which bore out this result. A source of protein in the shape of ordinary beef muscle, finely divided, was taken to the amount of 300 grams and allowed to remain in the stomach of a normal individual for forty-five minutes; then, by stimulating the pharynx, the material was recovered, incubated, and administered through a nasal tube to pernicious anaemia patients. A complete duplication qualitatively was found of the phenomena anticipated with liver or liver extract. Ten cases were so treated, and in all but two of them the expected response of reticulocytes appeared. There were special circumstances attaching to the two cases which did not show the response. The meat itself did not contain anything which was capable of evoking such a response, and it was therefore thought possible that the effective principle was supplied by the normal gastric mucosa, which had operated upon the protein, and from further experiment it appeared to be

demonstrated that the response was due to an interaction between the normal human gastric juice and the beef muscle. It was then desired to find out what was the exact type of interaction which took place, but the experiments with this end in view had not yet been completed. The normal gastric contents included gastric juice, swallowed saliva, and occasional traces of duodenal contents. It had been possible to show that the swallowed saliva had nothing to do with the action. The general result of the experiments so far was to prove the importance of interaction between, on the one hand, some substance which was thermolabile, and which was destroyed under the same conditions as those under which the enzyme activity of gastric pepsin was destroyed, and, on the other hand, a protein which might be obtained from beef muscle. It had not been possible to show that this reaction occurred generally with enzymes operating in an acid medium. Patients were given beef muscle which had been incubated *in vitro* with hydrochloric acid and commercial pepsin, but the results were negative, and the commercial pepsin did not work. The general result of the experiments was consistent with the hypothesis that this reaction was a digestion of the protein made by an enzyme working in an acid medium, but possibly only natural human pepsin was effective in this respect. In conclusion, the speaker mentioned the parallel between diabetes and pernicious anaemia. In diabetes the pancreas was the organ at fault, and the physiological defect was the internal metabolism of carbohydrate; in pernicious anaemia the defect was in the external manipulation of the protein, and the stomach was the defective organ.

Dr. HURST mentioned, in addition to the three cases given by Dr. Castle of pernicious anaemia developing after gastrectomy, one other case recorded by Ellis, in which the patient developed pernicious anaemia five years after the operation.

OBSTETRICS AND GYNAECOLOGY.

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Leeds on May 24th, Dr. A. M. CLAYE read a paper on "The puerperal morbidity rate in cases delivered normally: a comparison between cases examined vaginally and cases not examined vaginally." This will be published in full in a later issue.

Hypernephroma of the Ovary.

Mr. W. GOUGH (Leeds) showed a specimen of hypernephroma of the ovary. The patient was a married woman, aged 25 years. She had been normal as a child, but when seen she had a deep bass voice, and had to shave daily. The menses had appeared at the age of 13, and were regular up to the age of 20, when they ceased, and the changes in secondary sex characteristics began to appear. Her sexual feelings were normal. A mass, separate from the uterus, was found in the left iliac fossa, and there was some free fluid. On July 25th, 1928, abdominal section was performed. Two or three pints of straw-coloured fluid escaped, and a tumour of the left ovary, which had no adhesions, was removed. It was of bluish colour with pinkish orange excrescences on its surface. The right ovary and uterus were normal, and there were no swellings in the kidney regions. The tumour was reported as a typical hypernephroma. Twenty-eight days after operation the menses appeared. They next occurred a fortnight later, and thereafter were regular. As she last menstruated on April 6th she may be pregnant.

Dr. STEWART (Leeds) said the tumour was a simple benign hypernephroma exactly similar in structure to an adenoma of the adrenal gland. Dr. LEITH MURRAY (Liverpool) asked if male characteristics occur with unilateral renal hypernephromas, and said he thought Glynn asserted that they only occurred with bilateral tumours. Dr. Leith Murray had seen a case of sudden change in sex characteristics in a girl aged 25 in whom no abnormalities in the pelvis or the kidneys could be found. He asked if the cells in this case could be paralutein cells. Dr. STEWART said she did not consider that the cells showed the characteristics of paralutein cells. It was not necessary for the tumours to be bilateral to cause changes in sex characteristics.

Two Cases of Pyometra.

Miss RUTH NICHOLSON (Liverpool) recorded two cases of pyometra. The first patient was a single woman, aged 49, whose chief complaint was a constant vulval irritation for four to five years, and more recently a vaginal discharge. She had had cystitis as a child. The periods commenced at 14, and had always been irregular and scanty. She had not menstruated at all for the last five years. On bimanual examination thickening and fixation of the appendages was felt, and a diagnosis of tuberculous salpingitis was made. At operation very marked adhesions were found. The tubes were nodular, closed, and adherent to the ovaries. Panhysterectomy was performed. When the uterus was opened the cavity was found to be filled with a thick yellow pus. Microscopical sections showed typical giant-celled systems.

The second patient was a woman, aged 70, who had had a high amputation of the cervix eight years previously. She complained of a yellow discharge, partial rectal obstruction, and some vaginal haemorrhage. A mobile, solid mass, about the size of an orange, was felt continuous with the cervix. At operation, as soon as the vessels and cellular tissue had been cut across, the uterus broke away at the point where the previous amputation had been done. The specimen showed the uterine cavity distended with pus and lined with granulation tissue. Microscopically there was no evidence of malignant disease.

Puerperal Infection with B. welchii.

Dr. BURRIDGE (Leeds) recorded a case of puerperal infection with *B. welchii*. The patient was a primipara, aged 39, admitted to hospital with a diagnosis of prolonged labour and vomiting. Labour had commenced on March 21st, and on admission on March 25th her general condition was good: the temperature was 98.4° F., pulse rate 88. Vomiting had ceased, and no pains were present. The uterus was not tender, and no foetal sounds could be heard. The cervix was five shillings dilated, but not fully taken up. There was no change on March 26th, but by the morning of March 27th she was seriously ill, restless, of toxic appearance, and with a rising pulse. By noon the pulse was 120, the abdomen was distended, and the uterus tender. Preparations were made to assist the uterus to empty itself. The cervix was now half dilated, and an unsuccessful attempt was made to dilate it manually. This manipulation allowed the escape of a quantity of highly offensive gas, and some foul, frothy brown fluid. As immediate evacuation of the uterus was inadvisable axis traction forceps were applied, and a weight of 7 lb. was attached to the traction rods over a pulley. Pituitrin 4 minims was given at half-hourly intervals for five doses. These measures were successful, and by 5 p.m. the child's head was born. There was considerable difficulty with the delivery of the trunk owing to the enormous gaseous distension of the abdomen. Following delivery there was a free escape of brownish frothy fluid and much gas, but no haemorrhage. Swabs from the interior of the uterus, umbilical cord, and foetal abdomen gave a good growth of *B. welchii*. The patient stood delivery well, but in the evening restoratives were necessary. The next morning she was a little better, but the placenta was still in the uterus. It was left alone, as it was not causing symptoms. On March 28th 10 c.cm. Weinberg antigas gangrene serum and 40 c.cm. antistreptococcal serum were given. Further doses of antigas gangrene serums were given on the second, third, fourth, fifth, sixth, eighth, and eleventh days of the puerperium. Attempts to express the placenta on the fourth and fifth days of the puerperium were useless, but very painful. The patient remained *in extremis* for four days after delivery, and a change for the better was then noticed. Progress towards recovery was then remarkable, despite a vesico-vaginal fistula, which became manifest on the sixth day. By the seventeenth day the uterus was down to the pubis, and the lochia were scanty and non-offensive. The patient was sitting up on the twenty-first day, and walked a few steps on the thirty-fifth day.

The main points of the case are: (1) the absence of haemorrhage; (2) the fact that the placenta was never recovered would suggest that it was liquified; (3) the

retained placenta may have prevented the spread of infection; (4) the value of antigas gangrene serum.

Dr. CROFT (Leeds) remarked on another case which had been reported where a weight and traction rods were used to secure delivery. Professor CARLTON OLDFIELD (Leeds) mentioned a case of full-term ectopic pregnancy in which the child was extracted, but the placenta never came away. Later, this patient had an operation for ventral hernia, and no trace of the placenta could be found. Dr. STACEY (Sheffield) commented on the method of delivery as being useful in cases where there were no pains, and a dead child, in the presence of infection of the mother.

Dr. KING (Sheffield) had had three cases of *B. welchii* infection, none of which had recovered. He thought the conduct of labour in this case had been admirably conservative. He believed the idea of forceps *plus* a weight to be a valuable one, but that it had dangers, as witness the vesico-vaginal fistula in this case. He thought that labour ceased because there was an oedema of the uterine muscle, which caused paralysis. He had had a case in which he left the placenta *in situ*, and on the tenth day a portion about the size of a five-shilling piece was passed, and that was all. He considered that in the presence of a gas-forming organism tissue destruction must be much more rapid. Dr. LEITH MURRAY (Liverpool) had seen two cases of gas gangrene infection, both of which were fatal. The distressing feature he noticed was that the patients were acutely conscious although their bodies were really dead.

Dr. BAILEY (Leeds) had seen a number of cases of retained placenta. He always left the placenta alone in the absence of symptoms. Altogether he had had about thirty cases, and quoted some in which the placenta came away at varying intervals from thirty hours to six days, and one case where the woman would not allow him to examine her or to see the lochia. In this case, to the best of his knowledge, the placenta never came away. She was seen in his surgery two months after her confinement, quite well.

ENTERO-VESICAL FISTULA.

Professor CARLTON OLDFIELD (Leeds) reported two cases of entero-vesical fistula. The first patient was originally seen in 1914. A diagnosis of diverticulitis was then made and a pelvic abscess drained by posterior colpotomy. In 1928 the patient had three attacks of pain at different times, and after the third attack began to pass faeces and flatus from the bladder. This made the speaker still more certain that the condition was diverticulitis. The patient now had so much trouble that something had to be done. No information was obtained from cystoscopy. Abdominal section was performed and very dense adhesions were found. Eventually the bladder, uterus, and sigmoid were separated and a stony hard swelling was found adherent to the uterus and sigmoid. This was eventually separated, leaving a hole in the sigmoid, and a track lined by granulation tissue was discovered leading down to the bladder. The track was scraped and the hole in the sigmoid closed. The patient later developed obstruction, which was relieved by a caecostomy, and thereafter she made a good recovery. The report on the nodule was "typical, caseating, active tuberculosis; some parts of ovary, and plain muscle, are present." Professor Oldfield thought that the original lesion must have been tuberculous salpingitis.

The second case was one in which a vesico-vaginal fistula followed a Wertheim's operation. The fistula was repaired and a few days later urine was being passed per rectum. No further treatment was undertaken for this patient, and she remained quite well. Her only disability was the necessity for frequent bowel actions to pass urine.

RADIUM TREATMENT OF BUCCAL CANCER.

A MEETING of the Surgical Section of the Royal Academy of Medicine in Ireland was held in Dublin at the Royal College of Physicians on May 26th, with Mr. R. A. STONEY in the chair.

Mr. WALTER C. STEVENSON, in a paper on radium technique, said that unless those who used this powerful agent had suitable apparatus, and fully appreciated the physical properties which govern radiation, disastrous results would follow. This note of warning was necessary in the present boom, when those without previous experience might be tempted to employ this agent. He dealt briefly with the importance of obtaining uniform radiation and efficient treatment without over-dosage, and the risks of stimulating a growth by too small doses. He advocated the closest co-operation between the "radio-surgeon" and the specialist when carrying out surgical procedures in special branches, as in the throat or gynaecological conditions.

Mr. Stevenson showed six patients; in three of these an apparent clinical cure of cancer of the tongue, involving the floor of the mouth, and one of cancer of the lip, had been obtained by inserting six iridio-platinum needles containing 53.93 mg. of radium element, combining this treatment with surface application. A cancer of the tongue, in which a cauliflower growth had already disappeared, had not yet healed, the patient only having been treated about ten days before. A recent case of extensive cancer involving the whole upper lip and mucous membrane of the cheek, was also shown, in which twelve needles, containing 1 mg. of element each, had been employed in three positions, or thirty-six foci, during eighteen days. This patient had so far done remarkably well, all the growth in the lip having disappeared, and most of the growth in the cheek.

The CHAIRMAN said that, although some of the cases shown by Mr. Stevenson could not at present be claimed as cures, others appeared to be clinically cured, though it was not possible to say whether there would be a recurrence later on. In cases of carcinoma of the tongue there was at present a great tendency to recommend radium rather than operation. Operation in these cases entailed considerable risk, and if it was possible to get something which was at least as certain of doing good and of preventing recurrence he thought it should be recommended. When, however, he came across a case of early cancer of the tongue which could be removed by a partial excision of the tongue he did not feel justified in advising radium treatment, as in these cases it was possible to remove the growth at operation without producing any material deformity, and cure could be promised. There was also a certain class of case in which great assistance was derived by either radium treatment or *x*-ray treatment in rendering inoperable cases operable.

Dr. M. HAYES, referring to the complexities of radiotherapy, said that a tremendous amount of damage would be done unless those employing radium treatment would be guided by persons with previous experience of it. The physics of radium should be thoroughly understood by those using it in the treatment of disease. One of the chief dangers was radium burns, but unless the dose had been greatly excessive most of these could be healed by the application of normal saline solution. Referring to the problem of radium therapy *versus* operation, he said that if a malignant condition was operable surgery was preferable to all or any forms of radium treatment. Time alone would settle which was the best method. In cases of cancer of the tongue he thought radium treatment was preferable to operation, as after the treatment the tongue and speech were normal, and there was not the risk of deformity which surgery entailed.

Mr. C. J. MACAULEY said that cases of epithelioma of the lip, whether early or late, benefited by surgery, but as cases of carcinoma of the tongue and floor of the mouth were practically never seen in the early stages they did better by radium treatment. He always prepared such patients for radium treatment by getting any bad teeth removed and excising the glands in the neck; he thought it was a great mistake to treat these cases by radium without carrying out an extensive excision of the glands in the neck beforehand. Operations for cancer of the mouth carried a very high mortality, left the patients very deformed, and did not ensure any better promise of lasting good than radium treatment. He thought that the outlook for these patients was very much better at present than it had ever been before, and that any growth which could not be freely excised should be treated by radium.

Mr. A. CHANCE said that in the present state of knowledge he was convinced that radium treatment was suitable for all cancers of the tongue, except in very advanced

cases, where cure by any treatment was out of the question and the use of radium would discredit its value. The ultimate results of surgery in cancer of the tongue were as bad as they could be, and time alone would show what were the ultimate results to be expected with radium. On the established facts, radium should be the method of choice even in the earliest growths. The toilet of the mouth should be carried out before radium application. To extract a septic stump after radium application was to ask for septicaemia, as the vitality of the surrounding irradiated tissues favoured its development. There were reports in the literature of fatal results so brought about.

TUBERCULOMA IN THE FRONTAL LOBE.

Professor H. F. MOORE and Mr. C. J. MACAULEY showed a boy, aged 15, who, five years prior to his admission to the Mater Misericordiae Hospital, had sustained a head injury with a scalp wound in the left parietal region. Two years later he began to suffer from twitchings of the right side of the face, right eye, and right arm; the twitchings were preceded by an aura of taste, but the boy never lost consciousness. He had an attack while in hospital, and for some time after had considerable difficulty in speech. On examination an irregular defect could be felt over the upper part of the left parietal bone. There was paresis of the right arm with distinct astereognosis. The boy walked with a hemiplegic gait and the abdominal reflex was absent on the right side; Babinski's sign, ankle, and rectus clonus were present. Examination of the eyes revealed double optic neuritis with advancing atrophy, the latter being more advanced in the left eye. The Wassermann reaction was negative. X-ray examination showed convolutional atrophy but no bony depression. A diagnosis was made of a cerebral lesion involving the lower part of the left Rolandic area, possibly post-traumatic, and an operation was performed by Mr. MacAuley. A large scalp flap was turned down over the left fronto-parietal region. There was an irregular linear defect in the upper part of the left parietal bone, through which a bluish membrane presented; the defect was enlarged, the extreme thinness of the skull being noteworthy. The membrane, when incised, proved to be the dura mater, and some fluid escaped under moderate tension. The underlying brain was oedematous with flattened convolutions. Through the soft brain tissue one could palpate a firm nodular mass in the interior of the frontal lobe. The pial vessels were ligatured and the brain was incised. The tumour was then gently enucleated. It weighed 93 grams, and on section proved to be a tuberculoma. The boy made a complete recovery; he has had no twitchings since the operation, and power has remarkably increased in the right arm. Weakness in the internal rectus had now gone and the Babinski reflex was absent.

The CHAIRMAN said that the preliminary symptoms in this case were difficult to explain in view of the pathological findings. It was interesting to note the large size of the tumour and its consistency. Tuberculomas were usually small; as they got bigger they turned into definite abscesses. Mr. W. PEARSON thought the prognosis in this case was exceedingly good, and asked if there had been any urinary trouble. During the war he had seen a large number of frontal lesions, and the cases almost invariably suffered from disturbances of micturition. Mr. A. A. MCCONNELL said it was interesting to see a case in which it was possible to remove the tumour, and to find that such a large tumour turned out to be a tuberculoma. In his experience tuberculomas were rare, and the prognosis in the majority of cases was bad, owing to the presence of multiple tumours and the onset of dissemination. He thought that in the present case the patient would probably continue well; if there was to have been dissemination it would have taken place already.

Mr. MACAULEY, in replying, said he understood that the boy had at one time some nocturnal incontinence, but on admission to hospital this had disappeared.

NON-PARASITIC CYSTS OF THE LIVER.

Mr. F. MORRIN read a paper on non-parasitic cysts of the liver. He reported two cases of polycystic disease of the liver which had occurred in sisters during their third and fourth decade respectively. The family history revealed that the father died of pernicious anaemia, and a sister died at the age of 25 from some obscure abdominal complaint. One case was an abdominal emergency, a ruptured parovarian cyst being found at operation. The liver showed extensive polycystic disease, and, in addition, there were cysts in the transverse mesocolon and a cyst situated below the left kidney. The other patient complained of attacks of right-sided abdominal pain and vomiting. Operation disclosed polycystic disease of the liver and localized inflammatory reaction over some large cysts in the right lobe. In this case functional liver tests which were carried out showed no deviation from the normal. The varieties of cysts met with and the views as to their origin were mentioned. The familial association of the cases reported supported the view that the condition was most probably a developmental anomaly. Reference was made to the great difficulty in diagnosis, owing to the absence of jaundice and freedom from digestive disturbance; functional tests in one of the cases showed that the pigmentary, glycogenic, and excretory function of the liver was unaffected.

The CHAIRMAN said that polycystic disease of the liver and kidneys was of interest from an embryological point of view, and he had always been of opinion that these diseases must be due to some congenital abnormality. The fact that the fluid contained in the cysts was of a more or less non-biliary character suggested that it must be the product of cells not normally found in the liver. Mr. MACAULEY said that he thought a large number of cases of polycystic disease of the kidney were associated with polycystic disease of the liver. He wondered what the subsequent fate of patients with this disease was, and if death ensued from interference with liver function. Dr. A. B. CLERY remarked that Dr. Lindo had suggested that the disease was due to the maldevelopment of mesoblastic tissue in the fourth month of life.

Mr. MORRIN, in replying, said that according to the literature no necropsies had been performed in cases of polycystic disease of the liver except in children, but the oldest patient operated on for the condition was 82. In the great majority of cases the condition did not lead to early death, though the more severe cases died in early life.

RECIPROCAL CONTRACTION OF ANTAGONISTIC MUSCLES.

ON June 13th, at a meeting of the Royal Society, Sir CHARLES SHERRINGTON communicated a paper by Lady Briscoe and Miss Winifred Leyshon on the reciprocal contraction of antagonistic muscles in peripheral preparations —using a flashing neon lamp circuit for the excitation of nerve. It had been shown previously by one of the authors that all types of respiratory movement and different degrees of postural tone in the diaphragm could be accurately reproduced by varying the amplitude of a faradic stimulus. In this paper, illustrated by a cinematograph film, it was for the first time shown that reciprocal contraction of antagonistic muscles could be obtained in peripheral preparations by reciprocal excitation of the nerves of the opposing muscles. The electrical stimulation was carried out by using the regular intermittent discharges of a condenser in a neon tube flashing circuit. These discharges were passed either through a primary coil oscillating between two secondary coils, or through an arrangement of potential dividers, one of which consisted of a conducting fluid into which dipped an oscillating wire. Reciprocal changes in the stimuli were obtained by either of these methods, and it was shown that controlled and co-ordinated rhythmic movements of a limb closely resembling natural movements were produced by the suitable artificial stimulation of cut efferent nerves. If during this controlled rhythmic movement the mechanism producing phasic variation was stopped at any point, the limb remained held in posture. The method of stimulation was thus shown to be adequate for both movement and posture. An analysis of the forces controlling movement showed that the control of relaxation was as important for smooth co-ordination as the control of contraction.

Reviews.

DISEASES OF THE LIVER AND BILIARY TRACT.

THE sixteenth fasciculus—a bulky volume of more than a thousand pages—of the *Nouveau Traité de Médecine*,[1] edited by G. H. ROGER, the late F. WIDAL, and P. J. TEISSIER, is devoted to diseases of the liver and the biliary tract. It gives a well-illustrated account of the subject, with special reference to the many advances achieved by the work of French observers. It is written by thirteen contributors, among whom the late Professor F. Widal's name appears as responsible, with Professor P. Abrami, for the article on jaundice, which occupies a tenth part of the volume, and with Dr. Etienne May for a shorter but very considerable account of spirochaetosis icterohaemorrhagica. The volume opens with a description of the methods of physical examination of the liver by Professor Maurice Villaret and Dr. L. Justin-Besançon, who supply five other articles in the work, including that of 150 pages on the cirrhoses. Their account of the physical examination is accompanied by fifteen admirably clear illustrations, including skiagrams and outlines of orthodiagrams. As an introduction to his description of the symptoms of functional hepatic disorder Professor Marcel Garnier passes in review the functions of the liver, and the tests for hepatic efficiency; in their article on the syndrome of portal hypertension Villaret and Justin-Besançon, who later in the volume write on pylephlebitis, discuss the physiological and anatomical aspects of the hepatic circulation, and utilize much of the senior author's experimental work; the appearances of the collateral circulation in clinical cases are well illustrated by figures. In the article on jaundice the subject of haemolytic jaundice, on which Chauffard and other French writers have done so much, is handled fully and in an attractive manner, and attention is rightly drawn to the work of Aschoff and McNee. In the article on cirrhosis—a most valuable source of reference—the etiological influence of tuberculosis and syphilis is discussed, and whereas the former is regarded as unimportant, great stress is laid on previous syphilitic infection. Arguments against the existence of Hanot's hypertrophic biliary cirrhosis are well set out, and the various forms of Hanot's syndrome are noticed. Professor Legry's article on hepatic syphilis is generously illustrated with plates borrowed from works by the late Professor Maurice Letulle. For the account of hydatid disease the valuable services of Professor F. Dévé of Rouen, who has devoted so much attention to the subject, have fortunately been secured; of the rare alveolar form he accepts as genuine five cases only in France. The article on toxic hepatitis, in which reference to the late Benjamin Moore's work on trinitrotoluene is duly made, deals mainly with the effects of alcohol and chloroform, and two forms of the latter—benign and grave—are described. Diseases of the biliary tract are concisely dealt with by Professor M. Garnier and Dr. R. Prieur. In the section on gall-stones surgical intervention is admitted to be more efficacious than medical means of treatment. The concluding article in this instructive presentation, on perihepatitis and perihepatic abscess, by Professor Villaret and Dr. Justin-Besançon, is illustrated by fifteen skiagrams.

In a little volume entitled *Chirurgie des Voies Biliaires*[2] Professor SOBRÉ-CASAS of Buenos Aires discusses the results of cholecystostomy and cholecystectomy as usually practised, and describes several original methods in technique. In suitable cases he drains the gall-bladder after ligature of the cystic duct and of the cystic artery, and he finds that the results are superior to those of the ordinary procedures, in that in no case has the operation been followed by death or by any serious complications. In some cases he excises in addition the mucous membrane from the gall-bladder, leaving the outer coats in place. The details of the operative technique are shown in a series of admirable coloured drawings, which make the author's meaning perfectly clear, even without reference to the text. We would strongly recommend this little volume to the attention of all surgeons who are interested in this important branch of their art. It includes an extensive bibliography.

LOOSE-LEAF LIVING SURGERY.

THE *Nelson Loose-Leaf Living Surgery*[3] in eight volumes is produced in a way which makes its appearance a new departure in surgical literature. Most of those who have bought expensive treatises or systems of medicine or surgery have been struck with the appalling rapidity with which they grow old and obsolete, either in part or as a whole. He who has sold his obsolete Ziemssen's cyclopaedia of medicine for 3s. 6d. a hundredweight as waste paper is not easily tempted to invest in another library likely to become rapidly obsolescent. In many cases the symptoms of decay in usefulness are unequally distributed throughout the work, some sections remaining still valuable and authoritative, while others are as good as dead. Struck by such experiences, a number of physicians, in consultation with the publishers of loose-leaf books, combined to bring out a loose-leaf medicine, the success of which has encouraged Messrs. Nelson to bring out the work now under notice. If the expectation of the authors and publishers is fulfilled the epithet "living" will be justified, for the intention is to reject every portion of the work as soon as it becomes obsolete, and to substitute for it a new and up-to-date section, which will be supplied by the publishers as soon as it becomes necessary. In this way the book, like a living organism, should be constantly extruding worn-out parts and acquiring new ones in their place.

The list of contributors to the eight volumes is a guarantee of the value of their contents. It comprises more than seventy names, nearly all of which are those of American and Canadian surgeons, only five being European, and none of those British. The editor-in-chief, Dr. ALLEN O. WHIPPLE of New York, has been assisted by an advisory board of nine surgeons, among which the name of Professor George W. Crile may be taken as an indication of their quality. The first essay—on the history of surgery, by Dr. Alfred Brown—is probably the one most likely to be permanent and to survive the operations of the loose-leaf binder; and when the owner of a copy of this system is purging it of obsolete stuff, as in the words of Homer, quoted by Dr. Brown, "Through the thick files he darts his searching eyes," he will spare this fascinating essay.

It is not possible in a general review to make any attempt to criticize such a work as this. Its scale may be estimated from the bare statement that 269 octavo pages are devoted to the consideration of fractures and dislocations, and that over 100 pages are taken up with the surgery of the hand alone, giving to this region an importance which the gravity of hand lesions deserves, but which they very seldom receive. The illustrations are worthy of their subjects, and many are in colour. We wish Messrs. Thomas Nelson and Sons success in the bold adventure which they have undertaken in their revolutionary production.

[3] *Nelson Loose-Leaf Living Surgery.* Allen O. Whipple, M.D., Editor-in-Chief; Fordyce B. St. John, M.D., Associate Editor. Vols. i to viii. New York, Edinburgh, London: T. Nelson and Sons. 1928. (7½ × 7½; pp. xxii + 685; illustrated.)

TEXTBOOKS OF BACTERIOLOGY.

THE requirements of those seeking a handbook of general microbiology will be well suited by TANNER'S *Bacteriology*.[4] Its province is much wider than that of bacteriology from the purely medical aspect, for it essays to cover the whole field of the subject. And although there are sections concerning human ailments, they take but a minor part in the book, so small indeed as to be of little value to the medical man, as may be judged by the brevity of the paragraphs touching diphtheria and tuberculosis; the Schick and Widal tests are described, but there is no

[4] *Bacteriology.* By Fred Wilbur Tanner. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1928. (Med. 8vo, pp. xvii + 548; 138 figures. 22s. 6d. net.)

mention of the serological reactions in syphilis. Chapters of a general nature describe with some completeness the features of the biology of micro-organisms, such as their morphology and chemistry, their reactions to physical and chemical agents, and their interrelations with each other, with plants, and with animals. Students of public health will find interesting and instructive chapters dealing with the bacteriology governing questions of food preservation, the purity of water, and sewage disposal. There are abundant details of a practical kind regarding the handling of milk and the preparation of butter and cheese, and many points are discussed which concern normal and diseased foods. There is, finally, a description of the diseases of plants due to bacteria. The classification adopted and detailed with great completeness is that of the Society of American Bacteriologists, and particularly Bergey's modification of it, and there is also an outline for a course of lectures on the subject the book deals with. The English purist will find few Americanisms to cavil at, but he will not be alone in his surprise at the apparent redundancy in a glossary of such a word as health, defined naively as a state of well-being in body and mind, while the word bacteriophage is wanting. The definition of the word "homologous" as "having the same function" is dubious. The volume is sufficiently illustrated and indexed; the references, which are many, are chiefly to American literature. The history of the subject is not neglected and some biographical data are included. But it seems unnecessary, in discussing theories of disease, to do more than mention the demonic hypothesis; and it is remarkable that in describing treatment of disease by bacterins (a synonym for prophylactic vaccines) the author should ignore the pioneer work of Wright. Misprints are few, but "attention" for "attenuation" catches the eye; the names of Negri and Metchnikoff are incorrectly spelt. For the student of bacteriology as a pure science Tanner's book has many merits, although it will hardly meet the requirements of medical men in general, nor indeed does it address itself to them.

The appearance of a second edition of BIGGER'S *Handbook of Bacteriology*[5] within a few years of the original publication is the index of a popularity that is likely to continue. The literature of bacteriology is constantly and rapidly increasing, and when an author, sifting through it and holding fast to that which is good, combines the result with his own experience he performs a real service to medicine. Written in a style which is at once pleasing and concise, this book is very full of the information valued by the student and also appreciated by those working at closer quarters with bacteriology. About half of the pages are concerned with general matters, including the preparation of media, immunity, and serological technique. There follows an account of the classification of bacteria, and the remainder of the volume deals with the subject from the systematic point of view. This new edition has been largely rewritten and amplified. The matter is of uniform excellence and a due balance is maintained between theory and practice. The account of vaccine therapy and the chapter on tuberculosis are especially praiseworthy. Important and tried methods of investigation are adequately described (the Levaditi method for staining spirochaetes rather shortly, however), and there is a sufficiency of illustration and indexing, though it is unfortunate that the index of coloured plates errs in the numbering of the pages referred to. The book is certain to retain its good name as a manual.

SCIENCE, PHILOSOPHY, AND RELIGION.

FROM time to time men eminent for their scientific attainments attempt to reconcile the discoveries of science with the tenets of religion. Thus Sir Lauder Brunton once wrote a book to explain the miracles of the Bible, such as the parting of the waters of the Red Sea, and the halting of the sun for the benefit of Joshua, in the light of scientific observation. Modern study of psychology has enabled Dr. WILLIAM BROWN to approach the subject in a more philosophic, and perhaps less unconvincing, spirit, and in *Science and Personality*[6] he has presented a synopsis of views which he developed in lectures delivered in the United States in 1928, on the Dwight H. Terry Foundation.

Dr. Brown divides the chief mental attitudes towards existence into the logical, the aesthetic, the ethical, and the religious. The first three are concerned with the true, the beautiful, and the good. The last is the attitude of the individual towards the universe as something upon which he completely depends and to which he attaches ultimate value. To the universe man adopts an attitude of worship, looking upon it as a value absolute in nature, not relative. In developing his thesis Dr. Brown seems to adhere rather closely to the doctrines of Plato. His definition of religion is perhaps nebulous. Such a statement as "philosophy may be made a religion, and in so far as it is made a religion it is more than mere philosophy," suggests the need for better defined terms. He assumes that the individual comes into the world with the power of discovering values; that he has a desire for the conservation of the three ultimate values of truth, goodness, and beauty; and that his mind has a non-temporal aspect, in that it has the power of forming ideals of knowledge, of beauty, and of goodness, and of considering the extent to which actual experience falls short of these ideals. Religion, he says, corresponds to an adequate sense of true values. A system of sentiments is built up within one all-inclusive sentiment; and this master sentiment will be centred round one supreme object, which, Dr. Brown says, must be the universe as a perfected system, as the full realization of the good, the beautiful, and the true. He believes that in the advance of science religion is needed more and more to keep us from reaching views which are a mere caricature of existence, and are out of harmony with our deepest aspirations and feelings.

Dr. Brown ranges over a wide area of science, pseudo-science, and philosophy. He discourses on relativity and the quantum theory in a manner which leads Sir Oliver Lodge, in a foreword to the book, to describe him as an unusually competent amateur. In biology, which he regards as the most fundamental physical science, he explains the doctrine of emergent evolution. He believes that science leads on to philosophy and metaphysics. He connects mysticism with an immediate experience of union with the spiritual universe; and distinguishes personality from individuality in that the former carries with it an element of universality. He pleads for the view that dissociation is just as necessary in the mind as association; and that it only becomes pathological when there is failure of the normal process of dissociation. Dr. Brown disagrees with the extreme views of the Freudians, and the overemphasis of the sex factor. On spiritual healing he adopts a non-committal attitude, as is perhaps natural in one who sat on the Archbishop of Canterbury's committee. He seems, however, to lean to a belief in telepathy, although he says that it is something about whose conditions we know next to nothing. He includes in his book two chapters on some investigations he has made into psychical research through a medium named Mrs. Osborne Leonard. He seems to have convinced himself, from various happenings at the séances, that there was "something in it." But another case in which he investigated the clairvoyant capacity of a shell-shocked soldier makes us, we are bound to confess, a little sceptical of Dr. Brown's valuation of results. Sixteen observations by the clairvoyant soldier were compared with extracts from letters received from his wife and daughter. Dr. Brown finds about 50 per cent. correspondence. Careful examination of the patient's statements and the information extracted from the letters suggests that a reckoning of 25 per cent. correspondence would be more than generous.

Interesting though the book is, it leaves in us a feeling that the scientific philosopher is inclined to magnify the position of man in the universe, forgetting that most of the human characteristics upon which we pride ourselves may not, after all, be very far removed from those of other animals; and that the investigation of the pseudo-sciences needs a kind of judgement which the scientific philosopher does not always possess.

THE ACTIONS OF DRUGS.

ELEMENTS of the General and Special use of Medicaments,[7] by Professor PAUL TRENDELENBURG, is a small volume in which the author has set out extremely clearly the outstanding facts about the actions of the more important drugs, and his book resembles in some respects the volume *Useful Drugs*, which is published by the American Medical Association. Professor Trendelenburg abstains from all discussion on theories as to the mode of action of drugs; moreover, he makes no attempt to describe all drugs in modern use, the entry of capitalism into drug production having, he points out, resulted in the commercial exploitation of countless new remedies. The number of new drugs alone is sufficient to make an estimation of their relative value difficult; accurate judgement is rendered almost impossible by the manner of their advertisement. Professor Trendelenburg's method is to give in relation to each important drug a summary of its history, its physical and chemical characters, its fate in the body, indications for its use, its side actions and dangers, the mode of its administration, and a valuable but unusual feature, its price. The work as a whole forms an extremely useful textbook for students. Although the statements are condensed and dogmatic they are remarkably accurate, and the author's wide knowledge of his subject makes his opinions of great interest, even though they are presented in a very summary form.

NOTES ON BOOKS.

DR. KAHN'S textbook on *The Kahn Test*[8] gives an account of the use of precipitation phenomena in the diagnosis of syphilis, and a detailed discussion of the technical aspects of the Kahn test. It has been written for the use of laboratory workers, and the author expresses the hope that it will also be read by physicians employing the Kahn test in their professional work. The terminology of colloid chemistry is employed throughout; the book is clearly written, and may be recommended to those interested in the subject with which it deals.

It is not surprising that the *Essentials of Infant Feeding*,[9] written by Dr. E. A. BARTON of the Child Welfare Department of University College Hospital, has passed into a second edition, for it embodies scientific knowledge with the results of much experience and is full of sound advice expressed in clear language. This edition has been carefully revised in accordance with the advance of knowledge.

We have received from Dr. JEHANGIR J. CURSETJI of Bombay a copy of a pamphlet published by him under the title *Sub-Standard Lives and their Assessment in Life Assurance*. It consists of a series of articles contributed originally to an American periodical, and is intended as a companion to the author's *Pocket Guide to Medical Life Assurance*, of which a third edition is now in the press.

Radiation in Chemistry,[10] by R. ALAN MORTON, gives an account of the way in which radiations of all sorts—those of light, heat, and x rays in particular—find practical applications in industry and in scientific investigations of all sorts. The greater part of the volume is devoted to the chemical activities of light rays, and contains sections dealing with light sources and the measurement of the intensity of light, photo-chemical reactions and their applications in the photographic and allied industries, photo-electricity and luminescence, biochemistry, and light. The last section treats of x rays in chemical theory and practice. The author writes clearly, and has brought together a large amount of interesting information, quoting a great number of books and original papers as the prime sources of his volume. It is intended for the use of technologists in the first instance, but should appeal also to all readers interested in the manifold applications of radiations in art, industry, and therapy. Indeed, the author thinks it right to sound a warning note in his account of light therapy, and remarks on the "tendency, which has recently become apparent, to exaggerate the curative value of light. Actinotherapy opens up great possibilities for effective co-operation between chemistry and medicine, but investigation is much more necessary than propaganda; until we know more than at present caution is advisable, lest light therapy should suffer a great reaction and fall into the disrepute which overtakes panaceas."

Physics in the Food Industry,[11] by Sir WILLIAM HARDY, is one of a series of lectures dealing with the application of physics in industrial processes. The preservation of food by cold storage, which is the principal theme of the lecture, is a very vital commercial problem, and the ingenuity expended in solving it makes the subject one of general interest. When speaking of the freezing of meat the lecturer explains that if the frozen food is to remain palatable the chemical breakdown processes taking place after it has been thawed must be very like those in freshly killed meat. When the beef is frozen on a commercial scale this ideal is not achieved, since the ice phase which separates out is never completely reabsorbed on thawing, and thus we have unpalatable, dripping meat. By a most interesting series of experiments it has been shown that the injury which occurs is the irreversible dehydration of the colloidal systems of the muscle. If the meat is frozen at a higher temperature, and less ice is separated, the process is reversible and the water reabsorbed on thawing. The breakdown processes then proceed as they would in fresh beef. An illustration of this principle which should be of particular interest to physiologists was given by means of experiments on the frog's sartorius muscle. In this case the responsiveness of the muscle stimuli was used as an index of its normality. It was found that muscles frozen at a temperature higher than $-2°$ C. were still alive after thawing, whereas those frozen at $-2°$ C. or below were dead. A muscle which had had 78 per cent. of its water removed would freeze at about $-2°$ C., and it was thought possible that the irreversible change resulting in the death of the muscle at $-2°$ C. might be due to separation of 78 per cent. of its water as ice. Drying experiments were undertaken which showed that muscles could have 77.5 per cent. of their water removed, and, shrivelled and dead though they naturally appeared to be, could recover when placed in saline solution, reabsorb water, and become more capable of responding to stimuli. If, however, 78 per cent. of their water was removed the process had become irreversible, and they were in fact dead. It is hardly believable that this striking physiological confirmation of the physical theory of dehydration of the muscle colloids can be due to coincidence. In conclusion it should be said that this lecture, despite the amount of information contained in it, is both brief and readable.

The little book on visceroptosis by Dr. CHAUVOIS, under the title of *Les Dessanglés* [ungirthed] *du Ventre*,[12] gives a short account of the subject, and recommends physiotherapeutic measures in cases capable of correction, and belts, and especially a pneumatic pad, for incurable cases, which may thereby be relieved.

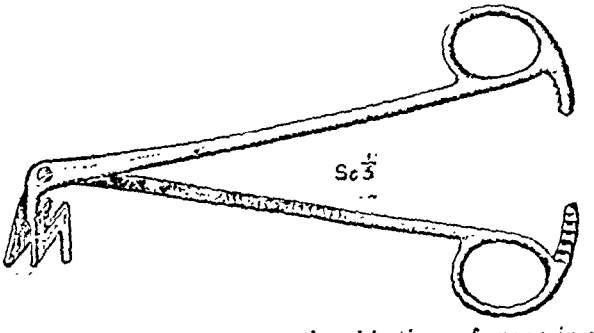
PREPARATIONS AND APPLIANCES.

PERITONEAL TETRA-TOWEL FORCEPS.

MR. W. McK. H. MCCULLAGH, *D.S.O., M.C.*, F.R.C.S. (London, W. 1), writes: The use of tetra cloths is now regarded as almost an essential in the technique of abdominal operations. The difficulty is suitable forceps. The forceps shown in the



accompanying figure overcomes the objections of many in use. It lies flat under the tetra cloth, as it has an abdominal curve. Its bite is also horizontal, and dips vertically into the wound over the skin edge. The fixation of the towel to the peritoneum is broad, and does not damage or tear the peritoneum. The instrument is sufficiently large to prevent possible loss in the abdomen. Two on each side are required for the average wound; the proximal two are attached by the operator with the assistant holding the peritoneal edge and towel edge in apposition, and the distal two by the assistant. They are of particular help in Caesarean sections. The forceps are made by Allen and Hanburys Limited.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

ANNUAL MEETING.

THE King Edward's Hospital Fund for London held its annual meeting (to which reference was made last week at page 1103) at St. James's Palace on June 11th, the Prince of Wales presiding.

In the course of his address His Royal Highness drew attention to the expansion undergone by the Fund during the past ten years. The distribution in 1918 was £200,000; in 1928 it had reached for the first time a total of £250,000. During that period it had grown into a central administrative body for the hospitals of London, and had the allocation of Sir Otto Beit's gift of £50,000 worth of radium. The Propaganda Committee had greatly extended its activities, and the publication entitled *Accounts for Small Hospitals*, prepared by the Economy Committee, was in demand not only in this country, but in many places abroad. A report had been prepared on the relations between the voluntary hospitals and municipal hospitals under the Local Government Act, and there had been important activities in relation to the Thank-offering Fund for the King's Recovery.

His Royal Highness then gave a summary of the principal data in the annual report for 1928, referring specially to the completion of the Wells legacies distribution, the start of the pensions scheme for nurses and hospital officers; the report of the Pay Beds Committee, and the allocation of the radium from the Beit gift. Lord Donoughmore, treasurer of the Thank-offering Fund, said that its figures had now reached £406,104, which did not include the £100,000 which had been given by the Government, on a pound for pound basis, to assist the radium part of the appeal. He moved a resolution expressing, on behalf of the General Council of the Fund, their heartfelt thankfulness for His Majesty's continued progress towards recovery, and the fervent hope for his early restoration to full health. His Royal Highness, in replying to a vote of thanks, which was moved by the Bishop of London and seconded by Sir William Collins, said that he knew the King would appreciate the kind words used by Lord Donoughmore, and the way in which the Council had received his resolution.

Report for 1928

During the year under review the total receipts of the King's Fund were £378,635, of which £40,852 was from the estates of the late Mr. and Mrs. John Wells. The amount for distribution was £250,000, an increase of £3,000 over 1927, apart from special pensions grants amounting to £9,452. Since the foundation of the Fund in 1897 a total of £6,109,306 has been distributed. With the Wells legacies, amounting to £255,092, the Fund has helped to extend forty hospitals, to rebuild four, to build three new ones, and to provide over 1,600 additional beds.

The report of the Pay Beds Committee, published in July, 1928, contained particulars of all the pay beds at the London voluntary hospitals. In March, eighty hospitals between them provided 1,005 such beds, and there were schemes to add another 900. The committee considered the methods of increasing accommodation and of providing for cost of maintenance and building, and recommended the organization of a mutual insurance scheme to assist persons of moderate means to meet the cost of maintenance and medical fees. It has been decided to compile in pamphlet form a list of pay beds in hospitals making returns to the King's Fund.

The superannuation scheme for nurses and hospital officers came into operation on January 1st, 1928, and by the end of the year had been adopted by 99 hospitals in London, and 77 outside London. The scheme, under which contributions are paid both by the institutions and by the staffs, and the pensions secured by insurance policies, was first recommended by a special committee of the Fund, and the details were settled by a series of conferences between the Fund, the British Hospitals Association, the Incorporated Association of Hospital Officers, and the College of Nursing. For seven years the Fund intends to make special grants, up to a limited amount, towards the expenditure incurred by hospitals on its books, and has set aside various sums to meet this liability.

Sir Otto Beit's Gift.

In allocating the Beit gift of £50,000 for the purchase of radium to be loaned to hospitals in London, the Fund gave preference to those hospitals in which the cure of disease was associated with interest in the furtherance of knowledge. Having placed an order for 4 grams the Fund proceeded to make a list of hospitals prima facie eligible; to inquire into existing stocks of radium at each of these hospitals and the specific purposes for which the additional radium was needed; to decide how much radium should be lent to the hospitals chosen; to approve the submitted specifications of the containers in which the radium for each hospital would be put up; to secure from each hospital the acceptance of the conditions of the loan; and to place orders for the putting up of the radium in the requisite form and to arrange for the testing of its amount in each container. The Distribution Committee decided to act on the principle that there should be a few hospitals with a sufficient supply to function as radium centres, and a larger number with sufficient to provide effective treatment to their own patients. Each hospital receiving a loan has been required to set up a Standing Advisory Committee to supervise its radium service; to submit to the Fund its rules for the use and care of the radium, and to send periodical reports showing all its stocks of radium, the milligram-hours of its use, and the number of patients treated. The radium, which in the first instance will be on loan for a period of a year and thereafter subject to withdrawal on due notice, is not to be removed beyond the hospital premises without the written authority of the Fund. At present, specifications covering 3.405 grams have been approved, while others amounting to 0.595 gram are still under consideration. It is stated in the report that in view of the long period taken up in the verification of the radium content of each container it would be some time yet before any of the radium is actually in use at the hospitals. The committee congratulates Sir Otto Beit on the foresight which led him, in dealing with his own generous gift, to adopt in the main the method to be used in the administration of the National Radium Fund.

Work of the Subcommittees.

With the object of ensuring that in the changes which result from the transfer of the Poor Law hospitals to the London County Council and other county authorities, the hospital service of the country shall not lose the features which are contributed by the voluntary hospitals system, the special committee of the Fund, under the chairmanship of the Right Hon. J. H. Whitley, prepared amendments to the bill, designed to secure co-operation between the voluntary hospitals and the county hospitals. In its memorandum, an account of which appeared in our issue of April 6th (p. 659), it suggested that this end could be achieved either by the presence on the appropriate committees of the county councils of persons experienced in the work of voluntary hospitals, or by provision for continuous consultation between those responsible for the two kinds of hospital, or by both methods taken together. The deliberations of the committee were still proceeding at the end of the year.

The Propaganda Committee records the assistance it has received from the press, the British Broadcasting Corporation, the film industry, medical and lay speakers, and many other agencies, in its work of spreading information about the achievements of medical science which are taking place in our voluntary hospitals to-day. During the year the net receipts from the committee's various activities have amounted to £1,142. The interest of the British Broadcasting Corporation in the King's Fund has steadily increased, and excellent results are being obtained by showing the hospitals film in conjunction with the general propaganda work of the Hospitals Savings Association.

Having considered various proposals that have been made with the view to lightening the burden thrown on hospitals by motor accidents, the Fund suggested that the most helpful way of dealing with the matter lay in encouraging motorists to include in their insurance policies a "hospital clause" with a small additional premium. So far, however, insurance representatives, in conference with the Fund, have put forward the view that the motoring public would not undertake a voluntary addition to the cost of insurance.

The Management Committee, having early in the year received applications for help from the hospitals situated within the Metropolitan Police district but beyond the eleven miles radius from St. Paul's, which is the present working area, took the opinion of all the other standing committees, and finally decided, with regret, that as the Fund had extended its radius as recently as 1925, it could not at present recommend the General Council to make further extensions.

Finances of Voluntary Hospitals.

The report concludes by drawing attention to the special need that exists at the present time to strengthen the financial position of the voluntary hospitals in order that their influence on the new developments in the hospital service of the country should be as great as possible. The annual distribution by the King's Fund is an important factor in maintaining the financial stability of these hospitals, and it is suggested that its power as a central co-ordinating body may be of the greatest value in the immediate future to all who desire the maintenance of the voluntary element in the hospital service.

RESEARCH DEFENCE SOCIETY.

STEPHEN PAGET MEMORIAL LECTURE BY PROFESSOR A. V. HILL.

THE annual meeting of the Research Defence Society took place at the House of the Medical Society of London on June 12th, with Lord LAMINGTON in the chair.

The report of the society's committee, which was presented, remarked on the fact that it was now twenty-one years since the society was founded by the late Stephen Paget, F.R.C.S., and it might be claimed that in carrying out the work of research defence it had rendered a distinct service to the community. The society, which was the only one of its kind in the country, had more than held its own against opponents, but the attention of members should be drawn to some new developments in antivivisection propaganda. For example, societies, instead of establishing shops, sent travelling vans loaded with literature and ghastly posters and exhibits into the country districts, and certain antivivisectionists were endeavouring to convert the Royal Society for the Prevention of Cruelty to Animals, with its huge funds, to a policy of antivivisection.

"*Enemies of Knowledge.*"

Professor A. V. Hill, Sc.D., F.R.S., delivered the third Stephen Paget Memorial Lecture, taking as his title "Enemies of knowledge." The advance of knowledge, he said, was something worth fighting for, because it was knowledge that made civilization. The position could not be held by standing still. It was necessary to combat the opposition to experiments on living animals. There was a limit beyond which intolerance, misstatement, and destructiveness must not be allowed to go. Medical men had their feelings, like the rest of humanity; some of them might be selfish or intolerant, but their general aspect was one of great friendliness. The reason he was standing up to defend his colleagues in the laboratories was because such a course had become an urgent necessity. When work done by the Medical Research Council was denounced by a priest, when the public were asked not to subscribe to hospitals lest the money be spent in torturing cats and guinea-pigs, when Ministers of the Crown allowed their names to appear as vice-presidents of antivivisection societies, the time for a counter-move had surely come. Instead of answering preposterous falsehoods by mere denials—remembering that when mud was thrown some of it stuck—it might be well to inquire what were the motives of those who circulated such falsehoods, what was the mentality of those who made them. Stephen Paget's generous heart and fighting spirit led him to join issue with those who combated the work which led to the discoveries that were the basis of so much mitigation of suffering.

Antivivisection was only one aspect of a general phenomenon which had been known throughout history; it was, if one liked so to regard it, a mild form of mental disorder. It had expressed itself at various times in a wide range of forms—persecution, hatred, malice, perpetual treachery, many hindrances to man in his slow efforts to climb the ladder of civilization. Many denied evolution, preferring to believe that Adam arrived fully equipped and educated in the Garden of Eden, and immediately started to give an appropriate name to each of the creatures he found, to his own satisfaction, rather than that there had been at least half a million years of slow and painful trial-and-error amid the necessities of life—namely, growth, maintenance, and production. What were man's methods of advance? Were they inevitable? Or could they be influenced by conscious adjustment on his part? There were "superior" people who affected to decry civilization and organization; they would have scientific work abandoned; scientific research and engineering development were regarded by them as things unworthy of man's highest physical state. Professor Hill agreed that, even for the best of causes, it was well to have to bear the brunt of criticism. He certainly did not favour making progress into a false god. Most people did not believe in magic, but realized that man's achievements had been won by eager search and patient toil, by failures as well as success. This desire for advancement was something to be regarded as sacred, as entitled to a high respect, even as was life itself. The advance of knowledge was a real thing, something well worth working for and fighting for; that was why that meeting had gathered, why this society had been established. We were still far from Utopia, either mental, moral, or physical. What made man superior to the animals was knowledge tempered by reasonable sentiment and controlled by decent emotion. All Governments paid at least lip service to education and service; the danger lay in special applications, not in the general proposition. Conflict arose when a piece of knowledge did not harmonize with vested interests, with inherent conservatism or natural cupidity; and the fight must always be against prejudice.

The Research Defence Society sought to promote national health and efficiency, and bring about a better understanding of medical and surgical studies and expose the false statements continually being made. Occasionally it was necessary to view the matter from a broader standpoint, to stand for the defence of research in whatever form that research was undertaken. There existed many "antibodies" apart from those in the human organism which were stimulated by infections and saved the patient from serious disease and death. Some of the social antibodies were comparatively harmless. There were, in London, four antivivisection societies, all fighting against one another in what they regarded as the same great cause. In 1835 there was formed an anti-railway society, and the editor of the journal devoted to it claimed that he was fighting for the truth. The subscribers to the anti-railway struggle included the provost and fellows of Eton College, fifteen canal companies, and a representative of a road transport company—all strenuously desirous of getting only the truth. However, false prophets could usually be trusted to cut each other's throats. Some people by their erratic behaviour amused, but it became a different matter when they threatened the State or the lives of their fellow men; society then had a way of removing them from the possibility of doing harm. If people by petty persecution in private, or malicious prosecution in a police court, provided a hindrance to the advance of knowledge, the matter ceased to be a joke, it must be taken seriously; and if a woman, to forward her thesis, did not hesitate to stop subscriptions to hospitals, and tried to stop the work on behalf of suffering humanity, it caused his blood to boil, and a feeling of tolerance to such became impossible. There was evident a desire to kill or seriously injure those whose opinions differed from their own; it was manifested all along the ages, and unfortunately was often linked with the name of God. In the parish magazine of St. Jude-on-the-Hill, Hampstead Garden Suburb, of May 24th, the incumbent asked intelligent people to take the opportunity of the General Election now past to put an end to the waste of public money involved in medical research, protesting against the spending of £148,000 during the last financial year by the Medical Research Council. Those who knew the splendid work being done by that Council to prevent suffering would wish to protest against that kind of propaganda. An advertisement in the *British Weekly* of May 16th last asked: "Will God allow the interests of humanity to be served by violating all His law of compassion; is blessing likely to rest upon such barbarities as baking animals in ovens and watching through glass doors to see how long they take to die; tying dogs' limbs over their backs and placing them in plaster-of-Paris and keeping them thus for six weeks?" The tendency of those who knew the facts was to laugh at these outpourings, but most of the readers probably did not know the truth. It was, said Professor Hill, possible to hold strong views and still be tolerant. What he was fighting against was calumny, persecution, attempts at legal interference with liberties, efforts to hinder co-operation in the cause of the greatest of human quests, the alleviation of suffering.

A number of questions were put by two women members of the audience on experimentation generally, without reference to the lecture, and also by Dr. A. S. MCNEIL. These were answered in an atmosphere of great excitement, and the end of the meeting was reached in considerable turmoil.

British Medical Journal.

SATURDAY, JUNE 22ND, 1929.

CLINICAL METHODS AND MAXIMS.

THE study of clinical medicine is, in the first place, the observation and recognition of particulars. The facts are gathered at the bedside of the individual patient, and the student must be trained to mark and appreciate them. Here the teacher, not less a student because of his seniority, enjoys his first opportunity: it rests with him to develop in his pupils the capacity to note facts and accurately to record them. The next step is the interpretation of the facts as this is justified partly by a knowledge of physiology—normal and disturbed—and partly by accumulated and disciplined experience. The process is an exercise in inductive reasoning guided by truths or doctrines founded on a wider survey than that offered by the individual case and on the knowledge of the teacher who has enjoyed this wider survey. The facts duly observed and set out form the clinical problem, and the teacher has to guide himself and his pupils to the solution of this problem by the application of maxims or general truths drawn in part from science, and in part from clinical experience. To these general truths the student must in the meantime give not only an attentive ear, but also a willing acquiescence. The time may perhaps come when he will be free to challenge them, but this time is not yet. He is still, for his own benefit, in leading-strings, and he may count himself fortunate that much of the accumulated experience of his predecessors can be summed up in certain general propositions which offer themselves as guides to his early steps. Still more fortunate is he if his teacher can present these propositions in a fashion that appeals successfully both to the memory and to the judgement.

It is on this sound basis that the student passes in due time to face for himself the clinical problems of private practice. Many of these, as he will surely discover, refuse to present themselves as the exact counterparts of his previous experiences. None the less he will be competent generally to deal with them provided he has trained himself to accuracy in observation, and provided also that he recalls and appreciates the summaries of practical wisdom which his teachers have pressed upon his attention. Indeed, it may be fairly said that in proportion as these two conditions are satisfied the junior practitioner has the qualifications necessary to fit him for independent practice and for the utilization of further experience as the training ground for increasing efficiency. Not that the rules or doctrines of any teacher are permanently to bind him either in opinion or in practice. On the contrary, he may well examine and test rules in the light of his personal application of them, always remembering, however, that though the traditions of the elders are not invariably infallible, there is at least a presumption in their favour. To give them their most modest status, they are useful guides to youth until the arrival of that proud moment when youth can show that the new day can boast its brighter light.

If this brief summary of the method of clinical training is justified, it follows that the teacher of this method has towards his pupils two responsibilities: first, to guide the pupil to cultivate his powers of observation so as to secure a full and accurate record of facts, the training here including in some directions the use of certain instrumental devices; secondly, to provide and to emphasize sound doctrinal truths based upon first-hand knowledge, and serviceable as guiding lights to correct diagnostic conclusions and to safe and successful practice. The importance of the latter task is undoubted, for the practitioner in his early career will have to meet new situations, and if he is to meet these successfully it will not be by recalling events of exactly the same order and degree, but by applying in each instance methods and principles capable of wide application and made familiar to him in his earlier training. To develop these methods and to define these principles is the teacher's task, and the responsibility is a considerable one. If patience is needed for the one aim, sound judgement is essential to the other. The pathognomonic sign or symptom, and the commanding and universal proposition—so tempting alike to teacher and taught—can rarely be announced in clinical medicine. Exceptions, restrictions, limitations, and individual peculiarities invade the attempt to define a number of rules having sharply presented and absolute values. Nevertheless some guiding directions of this order must be attempted, for otherwise clinical medicine is a mere multitude of particulars, and the student has no pathway for his steps. Hence a special measure of gratitude is due to those teachers who, having a wide and comprehensive view of their subject, cultivate skill in putting into summarized and attractive forms the lessons, not excluding the rebukes, that they themselves have gathered in the hard school of practical life.

A recent example of this important aspect of the art of teaching may be found in "More Medical Notes" written by Sir Thomas Horder and published in the current number of the *St. Bartholomew's Hospital Journal*. By no means the first venture in this field, these "Notes" are worthy to rank with the author's previous efforts and with the tradition of his school, and they definitely contribute to the security of his position in the ranks of the writers of medical maxims and aphorisms. The disadvantage of such utterances is that brevity and precision may be cultivated at the expense of comprehensiveness, with the risk that the trusting disciple will some day discover that the master's absolute rule has played him false. Sir Thomas Horder successfully avoids this pitfall. He knows that clinical teaching admits few hard and absolute propositions, and when he presents the general doctrine he presents also the exceptions, and, what is much to the point, he explains and defines these exceptions. To be the master who teaches, not the master who rules, is his ambition.

One of the texts included in the present series of "Notes" is pyrexia in malignant disease. Possibly taking origin in Wunderlich's classical *Medical Thermometry* of the early seventies, but put into terms more rigid than the original, the statement has often been made that febrile and even subfebrile temperatures exclude cancer from the diagnosis; or there is added the qualification that "uncomplicated"

cancer does not cause pyrexia—an unhelpful addition, for in practice the question is not, Is this a case of cancer with complications? but, Is it a case of cancer at all? Rapid growth of tumour, secondary (pyogenic) infections, absorption of products of tumour disintegration, may all be responsible for febrile records, so that given both a tumour and pyrexia the latter may not be successfully quoted in absolute opposition to a diagnosis of malignant disease. Indeed, the position may be put more strongly, for it is not too much to say that among the causes of apparently obscure pyrexia malignant disease ought to take a place. A hypernephroma, for example, may exist entirely without pain or other local discomfort, and be discovered only when a thorough examination is compelled by a series of abnormal temperatures. Similarly rigors, with or without recorded fever, may for weeks or months be the sole clinical evidences of malignant ulceration of the colon, and when in due time a "lump" is discovered the febrile readings may be quoted against malignant disease and possibly in favour of abscess.

Another maxim which Sir Thomas Horder commends to his pupils is that cancer is always to be suspected in the presence of progressive loss of weight and strength for which no adequate cause can be discovered, and he emphasizes the truth that in these circumstances cancer of the stomach is a possibility even in the absence of pain and vomiting. Again, it is well to have the proposition that, *pace* the popular press, a malignant growth is more frequent in the apparently healthy than in the subjects of long-standing dyspepsia or constipation. The smooth history of the first of these groups must not be allowed to quiet suspicion. There is another instructive doctrine to note—namely, that the first event to attract attention in the clinical history of a case of malignant disease may be the appearance of a secondary growth or growths, the primary tumour being small, or hidden, or overlooked. Some years ago the late Sir William Osler, in his papers on "The medical aspects of carcinoma of the breast," showed that this order of events may be true even in mammary cancer, and Sir Thomas Horder refers in this connexion particularly to primary tumours originating in the suprarenal gland and in the prostate. Yet again, if the patient has at some time had a malignant tumour removed, any subsequent clinical event may, or even must, give rise to suspicion, and the suspicion may be allayed only by the lapse of time. Particularly difficult in this respect are symptoms due to metastases in the central nervous system, as, for example, pains in the back or limbs, ocular palsies, and so on. Suggestive as such occurrences must be, quite a long time may be required before certainty in one direction or the other can be attained.

Apart from the truths they convey, and apart also from the manner in which these truths are stated, Sir Thomas Horder's "Notes" are welcome as examples of the doctrinal side of clinical teaching. After all, it is at the bedside that the art of medicine must be learned, for it is there that it has to be practised. The students who receive in terse and impressive sentences the carefully gathered experience of a physician who has cultivated a wide outlook on the large field of clinical medicine are not without good fortune, and sooner or later they will realize this. To formulate these maxims may appear a simple undertaking. Actually they involve much thought and not a little skill in literary craftsmanship, and a corresponding measure of gratitude is due to those who construct them.

THE MANCHESTER PROGRAMME.

THE provisional programme for the ninety-seventh Annual Meeting of the British Medical Association, which appeared in full in the *Supplement* of June 8th, will be republished, with additions and corrections, in a later issue. This year the clinical and scientific work is being divided among nineteen Sections, as compared with seventeen when the Association last met in Manchester in 1902, and their sessions will be held on Wednesday, Thursday, and Friday, July 24th, 25th, and 26th. In planning their business the sectional officers have kept in mind the advantage of concentration upon a limited number of topics; so much so, that more than half of the Sections have eschewed the individual paper altogether. Experience long ago proved that the haphazard acceptance of a number of communications on unrelated subjects did not usually lead to fruitful discussions. Thus it comes about that for next month's meeting no fewer than forty set debates are announced, and several of these—on abdominal pain, on tuberculosis of the larynx, on the influence of x rays in the healing of wounds, and on x-ray treatment of microbic diseases of the skin—will be combined discussions.

Taken as a whole, the nineteen programmes cover a very wide field of science and practice, and are commendably free from over-particularity or parochialism. No Section has laid itself out to flatter the specialist who speaks a private language and lives in a little world apart. On the contrary, the aim has clearly been to interest as many members as possible in each day's proceedings, and every Section appears to have chosen for consideration at least one subject of general interest. Indeed, the enterprising general practitioner, anxious for self-improvement, will find difficulty in deciding how to distribute his time to the best advantage. With so many competing claims he may well sigh for a multiple personality, which would allow him to attend at one and the same hour on Thursday a debate on the treatment of pleural effusion, another on abdominal pain, another on placenta praevia, another on chronic dyspepsia in school children, another on persistent nasal catarrh, another on bacterial food poisoning, another on conditions simulating phthisis, and another on the treatment of scoliosis; to say nothing of any desire he may have to keep up with new work in anaesthesia, ophthalmology, and radiology, or to extend his knowledge about river pollution and the present position of the voluntary boarder. Truly a varied and attractive bill of fare for a single morning; and if such are his perplexities on Thursday, the choice will not be much easier for him on Wednesday and Friday.

Between them the nineteen Sections this year at Manchester will hold some forty-five sessions, each of about three hours. On this as on previous occasions the *British Medical Journal* will have a reporter in every Section, but, even so, the preparation, printing, and publishing of the reports of forty-five sessions is a big task. As far as possible the opening paper of each discussion is put into print before the Annual Meeting, and copies are supplied to the honorary secretaries for distribution to members who wish to take part in the debate. These opening papers, and most of the independent communications read before the Sections, are published during the autumn and early winter. The debates are summarized by our Section reporters (with assistance from the speakers taking part in them), and their notes of the proceedings appear in the *Journal* immediately after the close of the meeting. The

purpose of this arrangement, which worked very well last year, is to give members who are not able to attend the discussions a brief but readable account of what is said, within a few days or weeks of the event, and to publish in later issues among original articles the full text of papers read to the Sections.

The Council of the Association provides an addition to the number of pages at our disposal during the autumn, to ensure speedy publication of reports of the work of the Sections. But this authority is not unlimited; the understanding is that it shall be exercised reasonably, and in the interests of the members at large. Even if we had space to record in detail the proceedings in forty-five three-hour sessions, our readers would not thank us for making the attempt. Taste has changed since the war. The medical man and medical woman of to-day have little use for the long-winded formal reports which in more spacious times dragged out their slow length, week after week, from August to February.

REGULATION OF TRAFFIC NOISES.

THE publication on May 10th of the report of the conference on road traffic noises and priority of traffic at cross roads has been followed by definite action on the part of the Ministry of Transport. It will be remembered that last October the Ministry convened a conference of local and police authorities and motor organizations, under the chairmanship of Sir Henry Maybury, to consider what action might be taken to mitigate traffic noises, above all those arising from the sounding of strident motor horns, and from the use of motor vehicles defective in design or construction, or carrying loads loosely or inefficiently packed. The Ministry had decided, in so far as it was empowered to do so, to make these matters the subject of regulation, and invited recommendations which could eventually be embodied in national and local legislation. In a recent leading article on noises and road traffic (May 18th, p. 915) we pointed out that the proposals made by the conference, though not completely in accord with those set out in the British Medical Association's memorandum on the same subject, went far towards being so. It must be admitted that the regulations of the Ministry of Transport, no less than the recommendations of the conference, fall short of what the Association would regard as the desirable minimum of control on traffic noise; they represent, however, the first effective recognition on the part of a Government department that this problem exists, and as such are whole-heartedly to be welcomed. The new Motor Cars (Excessive Noise) Regulations, which will come into force on August 1st, make it an offence for any person to use, or permit to be used, any motor car, or trailer drawn by a motor car, which, by reason of its design, construction, lack of repair, or load, creates any excessive noise. The onus of deciding what constitutes "excessive noise" will be placed in the first instance on the police, and then on the magistrates who will have to deal with charges under the regulations. It is at the moment a little difficult to imagine how a policeman in proffering a charge will be able to convince the magistrate that his judgement of excess is objectively valid, or how the magistrate, who has not heard the noise at all, will be able to assess its quality or intensity. If the fate of the motorist is not to depend on the whim of the policeman or the magistrate it would seem that some more precise definition of "excessive noise" is called for. The regulations provide that where a person other than the driver is responsible for the maintenance of the vehicle or for its loading, the driver shall not be held liable unless the noise could have been prevented by the exercise of reasonable diligence and care on his part.

The conference, our readers will recall, found itself unable to suggest a satisfactory method of controlling the use in urban areas of motor horns which have a strident or disagreeable note, and recommended further investigation of this matter from the technical standpoint. We are glad to note, however, that its proposal to forbid, in connexion with vehicles at rest on the highway, the use of any instrument for the purpose of giving audible warning, except on the grounds of safety, has been embodied in the regulations. In a letter addressed to highway authorities the Minister of Transport draws attention to the conference recommendations on precedence of traffic at cross roads, and suggests that their adoption will sensibly diminish the toll of road accidents. He points out, however, that the advantages which may be anticipated from a continuous and systematic application of these recommendations will be largely thrown away if the drivers of vehicles on main trunk roads are thereby made to feel that all other traffic must necessarily give way to them. The conference recommended the erection of special cautionary signs on subsidiary roads, but merely to warn drivers on those roads that they are approaching a special danger of which they might otherwise be unaware. The driver on the main road is not therefore absolved from the responsibility of exercising proper caution when approaching a cross road, and the use of the ordinary cross-road sign on the main route will not be discontinued. It was not to be expected that immediate action would be taken on the more elaborate constructive proposals of the conference—namely, those dealing with the planning of suitable types of lay-out at road junctions—but it is encouraging to note that the Minister of Transport has drawn the attention of highway authorities to these proposals, and suggested that when roads are being enlarged or new roads constructed sufficient land should be taken to enable junctions to be laid out in accordance with the plans the conference considered to be most appropriate.

HEALTH, DISEASE, AND INTEGRATION.

THE word "integration" is a favourite one nowadays with writers on health subjects. Its increasing use is perhaps a sign of the times, an indication of a tendency in medical men and others concerned with individual and public health to view the cognate problems from many standpoints, to leave none of their aspects unsurveyed, and to avoid concepts which achieve simplicity at the cost of comprehensiveness. In its medical, perhaps in its mystical, significance the word is thoroughly exploited by Dr. H. P. Newsholme in his recent book *Health, Disease and Integration*,[1] a speculative essay whose main theme is that the study of problems related to the origin and incidence of disease has been concentrated too much on the seed and too little on the soil, and that even where the soil is taken into account due weight is given only to certain of its constituents. Healthy integration of the human body, according to the author, demands a neuro-somatic balance, a well-regulated but elastic interplay between the nervous and somatic systems; and its maintenance is subject to a coexisting harmony between the emotional, the intellectual, and the spiritual aspects of the mind. Disease, or mal-integration, results from disturbance of the normal neuro-somatic balance, whether this be produced by factors intrinsic or extrinsic to the body. Dr. Newsholme in this connexion argues that current views on the origins and development of disease are too often dominated by the doctrine that unhealthy conditions of the human body are produced by extrinsic factors, to the virtual exclusion of the idea that even in certain specific diseases the factor

[1] *Health, Disease and Integration: An Essay Based on a Study of Certain Aspects of Encephalitis Lethargica.* By H. P. Newsholme, M.D., F.R.C.P., B.Sc., D.P.H. London: G. Allen and Unwin, Ltd. 1929. (Demy 8vo, pp. 227. 12s. 6d. net.)

disturbing healthy integration may be intrinsic and originate in the soil itself. In considering the case histories and circumstances of some twenty-four patients who came under his observation suffering either from encephalitis lethargica or acute poliomyelitis, the author was impressed with the fact that the recorded bodily and nervous phenomena followed, or were associated with, some form of psychical disturbance, whether mental shock, fear, suppressed emotion, or some other evidence of a troubled mind. Many other observers have noticed in encephalitis lethargica the frequency with which psychic aberrations form part of the syndrome, particularly as late manifestations. Dr. Newsholme, however, puts forward the hypothesis that the psychic disturbances may in some cases be sufficient in themselves to initiate the various symptoms of this disease, and that in other cases also, whatever the specific or non-specific factor of causation may be, the symptoms may be produced by a "psychical mechanism." As a step further he seriously suggests that under certain conditions of nervous activity following on acute emotion or cerebral irritation, a living "intrinsic virus" may be developed and prove capable of producing symptoms indistinguishable from those arising out of extraneous infection. The author, it may be noted, frequently reminds his readers that this concept of the etiology of encephalitis lethargica is not intended to supplant the more orthodox views, but to expand them. In various other diseases as well—for example, tuberculosis, cancer, rheumatism, syphilis, leukaemia, and the acute infectious diseases—he suggests that the mal-integration involving faulty metabolism is caused or influenced more generally than is credited by a disturbance of the psychic factor—spiritual as well as emotional and intellectual—concerned in the neuro-somatic balance. Indeed, he holds that often it is in the realm of the spirit that the stresses which dislocate the perfect poise of neuro-somatic integration ultimately arise. He pleads, therefore, that medicine, if it is to prove effective in ministering to the body, should be assisted not only by art and education, but by the resources of religion, that only in this way will the emotions, the intellect, and the spirit which affect the bodily state receive their proper attention. This is much more than the *mens sana in corpore sano* doctrine as generally preached: it is a revolutionary conception of integration in relation to health and disease.

THE BRITISH ASSOCIATION IN SOUTH AFRICA.

THE British Association for the Advancement of Science is holding its annual meeting this summer in South Africa, under the presidency of Sir Thomas H. Holland. It will celebrate its centenary in 1931, being one year older than the British Medical Association. The first part of the meeting will be held in Capetown from July 22nd to 27th; the second part in Johannesburg and Pretoria from July 30th to August 5th. At the inaugural general meeting in the City Hall, Capetown, the association will be welcomed by the Earl of Athlone, Governor-General of the Union of South Africa, and after the induction of the new president Mr. J. H. Hofmeyr will give his address as president of the South African Association for the Advancement of Science on "Africa and science." On July 23rd there will be a discussion on science and industry; on July 25th Sir Ernest Rutherford will give an evening discourse on the structure of the atom; and on July 26th Professor Julian Huxley will give a public lecture on evolution. At Johannesburg the association will be welcomed by the mayor; Sir Thomas Holland will give his presidential address; and there will be a public lecture by Professor G. H. F. Nuttall on yellow fever in Africa. At Pretoria public lectures will be given by Professor J. H. Priestley on "The growth of a tree," and by Professor A. S. Eddington on "The interior of a star." The scientific work of the annual meeting will be divided among thirteen sections. In the Section of Chemistry Professor G. Barger's presidential address will be on the relation of organic chemistry to biology. This section will hold a joint discussion with the Section of Mathematical and Physical Sciences on quantitative chemical analysis by x rays and its applications. The Section of Zoology will hold a joint discussion with the Section of Physiology on experimental biology, and another on the nature of life, in which the Section of Botany will also take part. Among the papers to be read to this section will be one by Professor H. B. Fantham on protozoa found in South African soils, and another by Dr. Annie Porter on the hookworm problem in South Africa. The programme for the Section of Anthropology includes an account of the Taungs skull by Professor Raymond Dart, and several anatomical papers on the native races of South Africa. In the Section of Physiology Professor W. E. Dixon will give his presidential address at Capetown on July 24th, on "Physiology the basis of treatment," and a joint discussion with the Sections of Physiology and Chemistry on vitamins will be opened by Professor E. Mellanby and Professor A. Harden. The papers to be read to this section when it reassembles at Johannesburg include one on the influences of light on physiological functions, by Professor A. D. Stammers, another on the effects of dust inhalation, by Professor Mavrogordato and Professor J. S. Haldane, another on some factors controlling the structure of the teeth and their susceptibility to caries, by Mrs. Mellanby, and another on cancer and diet, by Dr. S. Monckton Copeman; there will also be a joint discussion on problems connected with deep-mine ventilation, introduced by Professor Haldane. The Section of Psychology has arranged a joint discussion with the Section of Educational Science on psychological tests in relation to education and vocational guidance; Mr. F. C. Bartlett's presidential address will deal with the experimental method in psychology, and Dr. C. S. Myers will read a paper entitled "A new interpretation of adaptation." In the Section of Educational Science, under the presidency of Dr. C. W. Kimmins, Sir Richard Gregory will present a report on science and the school certificate examination, and discussions will be held on the teaching of science in schools and on the professional education of South African natives.

MEDICAL CARE OF THE SICK POOR.

IN commemoration of the work of Dr. Joseph Rogers, who, at the age of 35 years, in 1856, was appointed medical officer to the Strand Board of Guardians, and thenceforth, amidst much controversy, devoted himself to the improvement of the medical treatment of the poor, there has been established a fund, the accumulated interest of which is from time to time to be given as a prize for the best essay on "The care of the sick poor of this country, and the preservation of the health of the poor of this country." The first of such prizes has been awarded to Mr. H. J. McCurrich, F.R.C.S., whose essay[1] appears to have been written in 1926, since that is the date of the prize, but the introduction is dated January, 1929, and there are indications in the text that regard has been had in some degree to recent developments. This is important, for the value of such a work is much diminished if it is not up to date and quite accurate in its facts. At the very least, a three years' delay in publication requires footnotes pointing out where subsequent events have affected statements of fact or of opinion. Moreover, in appraising a work of this kind we are bound to take into account the breadth of view and impartiality shown in its expressed opinions and criticism. There is abundant evidence of much industry and consider-

[1] *The Treatment of the Sick Poor of this Country, and the Preservation of the Health of the Poor in this Country.* By H. J. McCurrich, M.S., M.B., F.R.C.S. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Cr. 8vo, pp. viii + 132. 5s. net.)

able care and thought on the part of the author, and his book will be found a useful compendium of interesting material connected with the history of its subject. Yet here and there we detect a certain lack of balance in judgement, and slight inaccuracies that point to an imperfect practical acquaintance with parts of the subject. One or two examples must be given. On the first page there is the statement: "At present legislation is under consideration to amalgamate all the medical services dependent on public funds"—a very inadequate indication of the effect of the Local Government Act in its relationship to public health administration, or even of the draft proposals issued by the Ministry of Health prior to the introduction of the bill. In the section on national health insurance the history of the introduction of the system and the attitude of the British Medical Association is calculated to produce an erroneous impression. It was indeed unnecessary to the author's purpose that this old controversy, now happily seen in better perspective, should have been revived. With regard to the administration and work of voluntary and Poor Law hospitals, which is clearly the author's main interest, and in connexion with which he evidently wishes to maintain a judicial attitude, it cannot be said that a wholly accurate picture is, in fact, presented. An interesting feature of his essay is the very wide connotation given by Mr. McCurrich to the word "poor." He takes it that "the sick poor include all those who are unable to make unassisted their own arrangements for their medical treatment, and the preservation of the health of the poor includes all public health schemes dependent on public money." This is perhaps legitimate when explicitly stated, but we think it would have been valuable to discuss how far this can be reconciled with the use of the word "destitute" in the Poor Law, and how far, and by what method, domiciliary attendance on the very poor should be provided. In a report lately issued by the medical superintendent of a large Poor Law hospital[1] it is claimed that "we can never refuse any case of illness, as the sick person at the gate is, in the more modern sense of the term, destitute for the time being of necessary medical service, and must be admitted." This raises at once in a very active fashion two questions which are over-ripe for a more practical and clearer discussion: (1) What is the proper relation of the municipal hospital and its staff both to the voluntary hospital and to the private practitioner? and (2) What change of administrative status of the district Poor Law medical officer is involved by the legislation now completed, and how can his domiciliary work be associated with both the work of hospitals and that of the national health insurance service?

FUNCTIONAL NERVOUS DISORDERS.

THE seventh annual report of the medical director of the Cassel Hospital for Functional Nervous Disorders[2] contains many items of interest both to the mental specialist and to the general practitioner. The medical director, Dr. T. A. Ross, while not denying the close relationship of toxaemic states with psycho-neurotic and psychotic symptoms, pleads for the adoption of a more cautious attitude in the matter of operative intervention. He points out that there must be some limit to the amount of search for toxic foci that is tolerable, and that in many cases where operation is resorted to the anticipated recovery does not come about. On the whole, the cases which he has quoted and analysed do not encourage the belief that psycho-neurotic symptoms are likely to be benefited by operation, and even where there exists an unmistakable connexion between the mental symptoms and the toxic absorption, as in the case instanced of a young woman suffering from phobias and anxieties whose symptoms were relieved by operation for old mastoid trouble, the indications for operation are, in Dr. Ross's opinion, identical with those in normal people. It is a feature of the reports of this hospital that no patients' cases are reported on until they have been away from the hospital for at least one year. Such a policy prevents premature conclusions being come to. During 1927, 190 patients were discharged from the hospital, and of these 161 were new cases; 99 suffered from various forms of psycho-neurosis, 43 from psychotic states, 3 were alcoholic, 7 the subjects of organic disease, and 9 classified under the head of "psychopathic personality." Of the psycho-neurotic group 81 were classed as suffering from anxiety states, 14 as hysterical, and 4 as compulsive obsessional. Out of the 91 psycho-neurotic patients, 70 reported themselves as well or improved; 58 were in the anxiety class, and 12 in the hysterical. The four obsessional cases did not improve. Many illustrative cases are quoted. The accounts given of individual patients are of much more use, and afford greater enlightenment than the accompanying group tables, although the latter show clearly that the results of the treatment carried out at Swaylands are highly encouraging.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE final programme of the nineteenth annual meeting of the Oxford Ophthalmological Congress has been published this week; preliminary details were given in our issue of March 9th. As in former years, accommodation has been offered at Keble College, and members will assemble there informally at dinner on the evening of Wednesday, July 3rd. The meetings will be held in the Department of Human Anatomy in the University Museum, and in association with them there will be an exhibition of ophthalmic instruments and apparatus. After the formal opening of the congress by the Master, Mr. Bernard Cridland, at 10 a.m. on July 4th, a discussion on diseases of the lacrymal apparatus will be introduced from the ophthalmological aspect by Professor Joseph Meller of Vienna, and from the rhinological aspect by Dr. J. S. Fraser of Edinburgh. The afternoon will be devoted to a series of demonstrations, and in the evening the annual dinner will be held in the Hall of Keble College. The morning of July 5th will be given up to short papers and the delivery of the Doyne Memorial Lecture by Miss Ida Mann, D.Sc., F.R.C.S., entitled "Some observations on the vascularization of the vertebrate eye." In the afternoon a discussion on the ocular manifestations found in head injuries will be opened by Mr. Hugh Cairns from the general surgeon's point of view, and by Mr. Charles Goulden from that of the ophthalmic surgeon. The closing session on the morning of Saturday, July 6th, will be given up to papers on clinical ophthalmology. Copies of the programme and other information may be obtained from the honorary secretary, Mr. C. G. Russ Wood (12, St. John's Hill, Shrewsbury).

IT is proposed to hold a Masonic lodge meeting on Tuesday, July 23rd, at 5.30 p.m., at the Masonic rooms in Cooper Street, Manchester, to which all medical men who are members of the British Medical Association and of the Masonic Orders will be invited. Further details of the meeting will be given in future issues.

THE honorary degree of Doctor of Laws has been conferred upon Sir Charters Symonds, consulting surgeon to Guy's Hospital, by the University of New Brunswick, Canada, of which province he is a native. Sir Charters has signalized the occasion by founding a prize in histo[illegible] in honour of James Simonds, the original English se[illegible] at the mouth of the Saint John River.

PUBLIC HEALTH EDUCATION IN RELATION TO TUBERCULOSIS.*

BY

WILLIAM BRAND, B.A., M.B., C.M.,

SENIOR MEDICAL COMMISSIONER TO THE NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

MORE than forty years ago, in Edinburgh, Sir Robert Philip started the tuberculosis clinics which have since been attended by thousands of medical men and women, through whom the message there inculcated has been carried far and wide. Edinburgh is entitled to make some proud claims in this connexion. From its tuberculosis dispensary the proper teaching on this subject has been disseminated, and having led the way with a chair of tuberculosis in its University, Edinburgh still sends out every year hundreds of men and women fully equipped to tell the public what is known on this subject.

Unfortunately, knowledge acquired is not always outpoured, and the direct teaching of public health principles to the people has not, as a general rule, advanced beyond the occasional or ceremonial stage. It is true, as Sir George Newman has pointed out, that the first form of education is the effective administration of the public health and medical services; but, at the same time, this machinery needs to be displayed, interpreted, and brought home to the people if their intelligent co-operation is to be gained.

The National Association for the Prevention of Tuberculosis.

In this connexion attention may be drawn to the work of the National Association for the Prevention of Tuberculosis, which was inaugurated by King Edward VII, when Prince of Wales, in 1898. The National Association is a voluntary, not a State organization, but it works in co-operation with all public health bodies. Its mission, which has been faithfully carried out for more than thirty years, was explained by Sir William Broadbent at its inaugural meeting—"to carry into every dwelling in the land an elementary knowledge of the modes in which consumption is propagated and the means by which its spread may be prevented, and thus to strengthen the hands of medical men throughout the country who are dealing with individual cases of the disease." The National Association is also able to-day to strengthen the hands of the central authority and of the local authorities in carrying out the national tuberculosis scheme.

It might be suggested—though not by anyone who knows the facts—that the propaganda work of the National Association would clash with or overlap that of the local authorities. So it would, in the absence of a perfect understanding between the two. But the creation of a universal interest in and knowledge of the prevention of tuberculosis is neither a one-man nor a one-department job; it is work for a team, and the bigger the team the better.

In 1926 the National Association launched a special appeal for funds to carry out extensive propaganda throughout the country. The appeal was entirely successful, and the result enabled four medical and two nurse commissioners to be appointed for this purpose. One of these medical commissioners has been touring Scotland for nearly two years, everywhere maintaining touch as far as possible with the medical officers of the local authorities, with private practitioners, and with all interested organizations and individuals. The nurse commissioners are following up the visits of the medical commissioner with a view to enlisting the co-operation of district nurses and others. Each of the medical commissioners has a caravan, fitted up with an interesting collection of exhibits, and including a cinematograph projector.

Principles necessary to be Taught.

What is it that such a National Association should teach?

In the first place, very large numbers of the public have only a faint idea of the purpose of the tuberculosis dispensary, or even where it is situated. Only by a perfect understanding between the people themselves, the medical practitioners of the area, and the dispensary staff can the functions of a dispensary be adequately discharged. The dispensary, for example, is the centre for diagnosis, from which the idea of the importance of early diagnosis and prompt treatment is to be inculcated. The public have also to learn that the dispensary is the place where such early diagnosis can be made, and that their own medical practitioner and the tuberculosis officer are intended to work in the scheme together.

The idea of the sanatorium also needs proper presentation. Many patients look upon admission to the sanatorium with gloomy forebodings, picturing a lonely institution in a distant part of the country, with stern nurses and unapproachable doctors, and the result of such forebodings is that they procrastinate under various excuses and lose precious time. It is a different story when, after a stay in the sanatorium, they return. But it is worth while to diffuse generally the conception of the sanatorium as a place where health is sought—and may be won—amidst pleasant surroundings and happy people.

Again, amid all the obscurities of tuberculous infection there are certain principles which can be taught. I think we must agree with Krause when he said, "It would seem the better wisdom to presume not at all upon a resistance, an acquired immunity, that must be of undeterminable and hypothetical integrity in any particular case. The only rational attitude is to protect all human beings, of whatever age, against exposure." By this is meant that every effort should be made to stop the dissemination of tubercle bacilli, and with this everyone will agree. The people should be told that any excretion or discharge from the body may contain germs of one kind or another and spread disease, and that all such excretions or discharges should be disposed of safely. The causative agent of nearly all the common infectious diseases, and of many of the epidemic nervous diseases, as well as of tuberculosis, may be conveyed in sputum. When this is made plain the proper and rational practice is laid down on a broad basis. The known tuberculous patient is not singled out.

The Formation of the Habit of Health.

When we studied physiology we learned about the law of facilitation or of habit, how when an impulse had passed through a particular set of neurones to the exclusion of others, it would tend to take the same course on a future occasion, and each time it traversed that path the resistance it encountered would be smaller. Education has been described as the laying down of nerve channels in the central nervous system while this is still plastic. The proper time to make permanent the habit of safe coughing and safe disposal of sputum is early childhood, and if such lessons are repeated over and over again during the years of childhood the nerve channels are laid down, and the involuntary reflex act is established. There is no reason, for example, why, as an automatic reflex act, a person should not put some cover in front of his mouth and nose every time he coughs or sneezes. It would become automatic if what might be termed "spray drill" were taught persistently during early childhood and school life.

A wealth of potential teaching talent exists in the medical and nursing professions, and if it were only mobilized and utilized an immense gain to public health would be the result. The public should be given information concerning resistance to infection, how few persons can expect to pass through youth and adult life without frequent contact with such infection, but that the hygienically educated person does not contaminate others, and that such person, being careful of the welfare of the community, is in no way to be feared or shunned. But the public has also to be told that infection may be distributed by others, many of whom are not aware that they have tuberculosis, or, knowing it, are careless or uninstructed or untrained. Infection, in the ordinary sense, is likely to end in manifest tuberculosis only when the organisms are assisted by contributory factors. These need not be enumerated to those I am addressing, but the public has to be informed as to the nature of these contributory factors or causes, and how to avoid them, and this necessitates a sound public health policy.

* A paper read at a meeting of the Tuberculosis Society of Scotland, held in Edinburgh, March, 1929. Abridged for publication.

Assistance for the Tuberculous Invalid.

Another respect in which the public needs information is with regard to the requirements of the dependent tuberculous invalid. The penalties of dependency and destitution in the case of the tuberculous patient have not yet been grasped by the community. Some patients, having had during their stay at the sanatorium full and proper diet, find themselves unable to provide what is necessary on their return to their homes. Food is only one of the requirements of the tuberculous invalid. In various ways he needs assistance in his continued fight against disease, and in order that that assistance may be given, the creation of a co-operative public opinion is necessary. Another very important piece of work is to urge those responsible for the health of the people to ensure by all means in their power a pure milk supply, one which does not carry tuberculosis.

All this that I have sketched is in reality the trend of the teaching of the National Association for the Prevention of Tuberculosis. The National Association is not oblivious of what is being done officially. This country enjoys the benefits of a highly organized public health service, one of whose units is the tuberculosis service, and not the least important of the functions of this official service is that of education in health matters, with special reference to tuberculosis. The sanatorium or hospital, and also the tuberculosis dispensary, are educational forces, but the teaching needs to be carried farther, into the patient's home (where the interest of his own medical attendant is necessary), and among his family and friends. This calls for home visitation, supplemented by central meetings, the organization of which latter is not a little difficult. In a busy tuberculosis dispensary, with an ambitious staff, the day is all too short for the hundred-and-one tasks to be faced each morning, and the staff may not feel inclined to arrange meetings, nor may they have the financial means to enable them to organize such, including, for example, the display of films.

In this respect the assistance of the caravans sent out by the National Association is warmly welcomed. The medical commissioners who are sent out go, as has been said, in the spirit of team work. They fully appreciate the fact that each area may have its own special problems. They work in co-operation with the medical officers of health, tuberculosis officers, and general practitioners, many of whom in all parts of the country have expressed their thanks in unstinted terms to the National Association for carrying out a programme of popular lectures in their areas. But, of course, it remains for those residing in the area to render permanent the value derived from the occasional campaign, and in this respect no one has a greater opportunity than the general practitioner. As health education plans become more clearly defined, there can be no doubt that general practitioners will shoulder the burden of preventing disease as cheerfully and thoroughly as they shoulder the burden of treating it.

TREATMENT OF MENTAL DISEASE.

MORISON LECTURES, 1929.

DR. R. DODS BROWN, F.R.C.P.Ed., physician-superintendent, Royal Mental Hospital, Aberdeen, delivered the Morison Lectures before the Royal College of Physicians, Edinburgh, on June 3rd, 5th, and 7th, taking as his subject "Some observations on the treatment of mental diseases." Dr. R. A. Fleming, President of the College, occupied the chair on each occasion. Dr. Dods Brown dealt first with the historical aspect of the subject, and then with certain methods of treatment recently introduced or revived.

Historical Aspects.

At the outset the lecturer quoted from ancient Egyptian, Chinese, Hindu, Greek, Latin, and Arabian writings, referring in particular to the views of Hippocrates, Celsus, Soranus, Aretæus, and Paul of Aegina. There was good reason to believe that many of the Greek and Roman physicians treated the mentally afflicted with great care and consideration. It was far otherwise in the succeeding centuries. One of those to protest against the abuses prevalent in this country in the seventeenth and eighteenth centuries was Daniel Defoe, who characterized the system as "the height of barbarity and injustice, and worse than a clandestine inquisition." These abuses persisted well into the nineteenth century, and readers of *Hard Cash*, written in 1863, would recall the dismal picture of life in private asylums presented by Charles Reade. Philippe Pinel (1745–1826) stood out in medical history as the first in modern times to treat the insane in a humane manner. Like most pioneers, he was met with much misrepresentation, ridicule, and hostility. The earliest of the reformers in this country were Tuke, Hill, and Conolly, and to this list might be added with justice the name of the founder of that lectureship, Sir Alexander Morison of Bankhead. The latter, in the face of much opposition, had begun a course of lectures on mental diseases in Edinburgh in 1823, and was far ahead of his time in his understanding and treatment of disorders of the mind. He recognized the benefit of beautiful surroundings, fresh air, sunlight, exercise, sea-bathing, occupation, amusements, and cheerful well-lighted apartments. A remedy he recommended was warm bathing, writing of it that "it tends to allay the tension and the agitation of the nervous system, and to soothe and to diminish an increased sensibility, both of which are very prominent symptoms in the insane state." He gave great consideration to the bodily health of his patients, ordering in certain cases special diet, acidulous fruits, and copious draughts of cold water. Only exceptionally did he prescribe alcohol, and he was no believer in administering drastic purgatives and emetics, as was customary at that time. Happily, it was now true to state that the patients in our mental hospitals were considered as persons sick in body and mind, and were treated as such. All so-called civilized countries, however, had not made the same advances.

Modern Methods of Treatment of General Paralysis.

It was questionable whether any method of treatment adopted for the relief or cure of mental disease had given rise to so much interest or to so extensive a literature as had the treatment of general paralysis by malaria, introduced by Wagner-Jauregg of Vienna. That acute fevers might bring relief to sufferers from mental troubles was known to the ancients, and Hippocrates believed that fevers, especially quartan fevers, relieved spasms and mental diseases. John Munro, in the eighteenth century, wrote that "an intermitting fever coming upon a madness of long standing has proved the cure of the madness." It was of interest to read in Sir Alexander Morison's lectures that he had observed in "dementia" that the occurrence of an acute disease had occasionally been the means of a cure. Stoddart had recently stated that the beneficial effect of malaria in insanity was discovered in 1248. Although Wagner-Jauregg suggested deliberate infection with malaria as a therapeutic measure in general paralysis in 1857, it was not until 1917 that he inoculated his first patient. In the interval he had experimented with various bacterial and non-bacterial preparations. It was now a historic fact that in 1917 Wagner-Jauregg inoculated nine general paralytics with blood infected with the *Plasmodium vivax*. Three passed into a complete remission which lasted for more than eight years, and three had incomplete remissions. The method had been in continuous use in Vienna since that time, and it was the claim of that school that 83 per cent. of early cases made a complete recovery. Few others were able to show such results, but there was general agreement as to the very great value of the treatment. In 1,377 cases treated with malaria, recently reported in the literature, 25.6 per cent. of complete clinical remissions and 30.4 per cent. of partial remissions were claimed. Thus 56 per cent. of patients were benefited. This contrasted very favourably with the percentage of spontaneous remissions, varying from 5 to 15, recorded by different observers. There was naturally difference of opinion as to the criteria of remission. Some were guided wholly by the mental improvement, others demanded, in addition, the disappearance

of all neurological findings, while yet others laid most stress on the serological findings. A survey of the results of malaria treatment of general paralysis in English mental hospitals had been made for the General Board of Control by Surgeon Rear-Admiral Meagher, and the lecturer had had access to the manuscript of the report. The results could be given in tabular form.

English Mental Hospitals (Meagher).

	1,173 Untreated Cases.		1,597 Treated Cases.	
		Per cent.		Per cent.
Dead	1,016	86 6	541	34
Alive	157	13.4	1,056	66
In hospital	117	10.0	652	41
Discharged	40	3.0	404	25

Meagher concluded by stating that, while malaria treatment precipitated death in a certain number of cases, it was valuable in extending life, in improving the mental and physical state, and in allowing some 30 per cent. of patients to resume normal life. The lecturer had also been fortunate in getting particulars of cases treated with malaria in Scottish mental hospitals. Excluding those that had received some form of specific treatment in addition to malaria, fifty remained for analysis. This figure included fourteen treated in the Aberdeen Mental Hospital. Twenty-four per cent. passed into a complete remission, 18 per cent. were greatly improved, 16 per cent. were slightly improved, and 22 per cent. died. Dr. Dods Brown then dealt in detail with the effects of the treatment on the serological findings, the technique of the methods of inducing malaria, the explanations offered of the mode of action, and the changes found in the brain in cases dying after the treatment. After a brief reference to the results of malaria therapy in other diseases, and to experiments with relapsing fever as a substitute for malaria, he passed to the use of other remedies in general paralysis and neuro-syphilis—namely, tryparsamide, arsenical preparations, salvarsanized serum, bismuth, mercury, agents producing leucocytosis, and foreign proteins.

Dementia Praecox.

After the success attending malaria treatment in general paralysis, it was natural that its effect should be tried in dementia praecox. Marked, though not always lasting, improvement had resulted in early cases, but the method was without value in old-standing cases. The experience in Aberdeen Mental Hospital had been unfavourable. Carroll and his associates in America, by repeated intrathecal injections of 25 c.cm. of inactivated horse serum, had tried to influence the course of the disease by producing a meningeal reaction, a sort of aseptic meningitis. In more than half of the forty-nine cases treated, there was decided benefit lasting for at least several months. Kubitschek and Carmichael made trial of this method in forty-five cases, and concluded that it held distinct possibilities in early cases. In four patients so treated in Aberdeen there was no improvement.

Heliotherapy and Actinotherapy.

These measures had been employed extensively in the Aberdeen Royal Mental Hospital in the attempt to benefit the mental through the bodily health. More than 200 patients had received one or more courses of ultra-violet irradiation. Seventy-seven per cent. had increased in weight, and the majority had shown improvement in muscle tone, appetite, and sleep, as well as in the blood picture. It was customary also to treat most of the recent admissions and many of the physically ill patients not only in the open air, but by heliotherapy, according to the graduated method of Rollier. The beneficent effect of this on the well-being of the patients was unquestionable.

Occupational Therapy.

For very many years patients in mental hospitals in this country had been employed on the farm, in the garden, the workshops, the laundry, the kitchen, the sewing room, and other departments, but the economic question was often the primary consideration, and the work chosen was not always calculated to enlist the interest of the patients. Occupational therapy, with the one object of curing or benefiting the patient, was no new fad. D. K. Henderson found from old reports that the directors of the Glasgow Royal Mental Hospital had referred to occupation as a means of cure in 1816. There was a note in the Aberdeen Mental Hospital records to the effect that male patients were employed in gardening, and female patients in spinning flax in 1810. About forty years ago craft work was developed in several of the larger mental hospitals in Austria, and for a considerable time the value of this means of treatment had been recognized in America and Canada.

In 1898 Hamilton Marr introduced craft work under the Brabazon scheme into Woodilee Mental Hospital. The idea was adopted in other institutions in this country early in the century, but fell into abeyance. It was only recently in Britain that interest had been revived in organized occupational therapy, and for this D. K. Henderson deserved most of the credit. It was desirable that the work should be carried out away from the wards in a special building which should be as bright and pleasant as possible. The complete change of environment was important. The department should be managed by a special teacher or teachers, who had nothing to do with the care and treatment of the patients in the wards. There should be a special annexe where noisy work, such as carpentry and metal work, was done. There was no limit to the variety of crafts that could be taught. In Aberdeen thirty different crafts were engaged in by the patients. The development of this means of treatment marked a very real advance.

At the close of the third lecture Professor G. M. ROBERTSON, physician-superintendent, Royal Mental Hospital, Edinburgh, moved a vote of thanks to Dr. Dods Brown.

FUNCTIONAL PROBLEMS OF CONVERGENCE.

SIR CHARLES SHERRINGTON'S FERRIER LECTURE.

THE contributors to a fund to commemorate the late Sir David Ferrier and his pioneer work upon the functions of the brain requested the Council of the Royal Society to accept the sum of £1,000 in trust for the institution of a David Ferrier Lecture. The Council, in accepting the trust, decided that the lecture should be given triennially on "a subject relating to the advancement of natural knowledge of the structure and function of the nervous system."

The first David Ferrier Lecture was delivered before the Royal Society, on June 20th, by Sir CHARLES SHERRINGTON, O.M., F.R.S., who took as his subject "Some functional problems attaching to convergence." The author's summary of the lecture is as follows:

The arrangement of the conducting paths of the nervous system, branching and redistributing their impulses as they do, exhibits places where numerous convergent paths run into one. When at such places two or more of the converging arcs are concurrently active, the trains of impulses arriving by them can interact. Such convergent places are co-ordination points. An example of such importance, and relatively accessible to experiment, is that in the spinal cord, where the motor nerve cells innervating a muscle receive as a group the various afferent paths which reflexly operate the muscle. If two or more of the convergent afferent nerves are excited concurrently the reflex interaction, as revealed by the muscle, exhibits three main sets of cases.

In one set of cases the muscular response under concurrent stimulation of two or more afferents shows a deficit in amount as compared with the sum of the responses obtainable from the several afferents taken separately. This occurs especially when the excitation of the reflexes is strong; it is most marked when they are of maximal strength. The contraction effect of one afferent may default altogether. The result might seem to indicate inhibition, but analysis shows that it is not referable to any form of inhibition. The explanation lies in the limita-

tions of the contraction response of the muscle fibres of the motor units activated: the contraction effect pertaining to one afferent being "occluded" for the time being by that pertaining to another. "Occlusion" is a result of the overlap of different afferent arcs upon the same motor units; this overlap is "central"—for example, in the spinal cord. The amount of "occlusion" as observed by the myograph gives a measure of the amount of that "central" overlap. In such estimates, however, the assumption is made that the component motor units of the muscle all of them possess individually the average value of contraction-tension which obtains for them. Thus in the knee-flexor (cat) semitendinosus has a value which is only one-third of that obtaining for gastrocnemius. It is, however, certain that the individual motor units differ considerably in contraction value within one and the same muscle. Examined by occlusion the overlap of the constituent branches of a single large afferent nerve upon its motor units can be well above tenfold. This gives a functional picture in harmony with the histological picture furnished long since by Cajal. In another set of cases, on the contrary, the contraction response of the muscle, under concurrent stimulation of two or more reflex arcs which are excitatory for it, shows a surplus of contraction as compared with the sum of the responses to the component afferents taken separately. This result is most evident with weak reflexes. As with the other set of cases this result also, although opposite to the previous class, brings evidence of the overlap of the convergent arcs upon the central ends of motor units held by them in common. Moreover, evidence is thus furnished that central states of excitement, individually too weak to provoke the motor units into discharging activity, can by summation become effective for that activation. The reflex excitation provoking contraction of the muscle is shown to be accompanied regularly in the spinal centre by concomitant subliminal excitation in other spinal motor cells over and above those excited to actual discharge. The time relation of central subliminal excited states obtaining in certain typical reflexes has been determined (J. C. Eccles). By the summation of subliminal excited states this fringe of subliminal effect is a functional means of liaison enabling co-operation between different adjuvant parts of the nervous system.

Although the neuron upon which convergent arcs interact is subject to their combined influence, and is to that extent an instrument passive in their hands, it is an instrument clearly with ways of its own. Thus, to receipt of a single stimulus it may react by a response consisting of a whole tetanic series of impulses. Another and third set of cases arising from interaction at the convergence point is where the upshot is inhibition. The clash is between "central" excitation and a central process which arrests or precludes it, but about which all that is known is that it antagonizes excitation. Evidence is adduced of the quantitative interplay of the opposed influences upon the individual neuron. Conditions favouring inhibition are discussed. Though trains of impulses are the sole reactions which enter and leave the central nervous system, it is clear that nervous impulses are not the sole reactions functioning within that system. States of excitement which can sum together, and states of inhibition which can sum together, and states which represent the algebraical summation of these two, are among the central reactions. The specific cell units, the neurons, far from behaving merely as passive recipients and transmitters of impulses, modify as well as transmit what they receive.

Union of South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA.]

Food, Drugs, and Disinfectants Act.

THE Parliament which has just been dissolved was remarkable for the amount of health legislation it effected. It was responsible for the final passage of the Medical, Dental, and Pharmacy Bill, which had come up repeatedly for a dozen years, but had invariably been dropped when opposition, designed chiefly to permit of unqualified practice, stiffened. Two amending bills to the Public Health Act of 1919 were passed, one in 1927 and the other in 1928. The Food, Drugs, and Disinfectants Bill—to consolidate and amend the laws for preventing the importation or sale of foods or drugs which are unwholesome or adulterated or incorrectly or falsely described, and for regulating the labelling and sale and for preventing the incorrect or false description of disinfectants—was first introduced in the House of Assembly in 1927. It was read a first time, but made no further progress. It was reintroduced last year, passed first and second readings, and was referred to a select committee. This committee took evidence and reported on the bill shortly before the end of the session. During the final session of the late Parliament the bill became law, and was published in the *Government Gazette* of April 3rd, as Act No. 13 of 1929. It is proposed to frame and publish regulations and standards under the Act by the end of next September, and to bring the Act, together with these regulations and standards, into operation as from January 1st next. This will allow a period of three months for anyone concerned to submit representations regarding the regulations and standards proposed. The bill as finally passed may confidently be described as the most complete and comprehensive legislation of its kind extant. The Minister of Public Health is responsible for the administration of the Act, and the Secretary for Public Health is charged, under the control of the Minister, with its general execution and enforcement. The need for consolidating and up-to-date legislation had been strongly urged in every annual report issued by the Secretary for Public Health, Dr. J. A. Mitchell, since the Union Health Department was constituted. Much evidence had been collected by the department showing the frequency of adulteration and the extent to which the public was being defrauded. As in the case of the old English Act of 1875, the local Acts made no provision for uniform standards except in the case of one or two articles of dairy produce. All these older Acts were framed to meet the frequency, at the time, of harmful adulteration. Nowadays harmful adulteration is rare, but the public has to be protected from harmless adulteration and sophistication of articles of food done with a view to making money. The Act aims primarily at safeguarding the public health, but important objects are also the prevention of fraud and misrepresentation in regard to food and drugs, and the promotion and encouragement of honest production and trade in genuine materials. Adulteration of a chemical nature is almost exclusively dealt with. Questions of unfitness for food—owing to contamination, putrefaction, or decomposition, or to the presence of parasites—are dealt with under the Public Health Act and also under the Municipal Ordinances of the four provinces. The Act does not impose any restrictions on the sale of patent medicines or other drugs, provided that there is no misrepresentation and that no extravagant and unwarranted claims are made on the label or in the advertisements. Standards are not laid down in the Act, but the Minister is empowered to provide these by regulations. This is a satisfactory position. Amendments to parliamentary legislation are often difficult and cumbrous matters to negotiate; regulations, on the other hand, can readily be modified to meet local and rapidly changing conditions.

Epizootic Among Rodents.

In the *British Medical Journal* of February 16th (p. 314) an account was given of the very fatal epizootic among veld rodents in the De Aar area, at first attributed to plague, but later found to be due to a Gram-negative, bipolar staining organism conforming morphologically and culturally to the Pasteurella group. Investigations were continued by the Union Health Department and the South African Institute for Medical Research. For two months after the heavy rodent mortality in the De Aar area had been notified, reports came in from regions further east of rats dying in large numbers. Thus, at the end of January, the magistrate of Calvinia, 250 miles east of De Aar, reported that "veld rodents were dying by scores" on certain farms in his district. From the information now available it appears that an area extending

from De Aar on the east to Calvinia on the west, with an average width of about 150 miles, was involved. This region is very sparsely populated, being for the most part sand veld with scant scrub. The rodent population consists mainly of Namaqua gerbilles (*Desmodillus auricularis*). These were the animals almost exclusively affected, and their numbers have presumably been very greatly reduced. This is a matter of much significance to the health authorities, as the ever-present danger to the human population from plague epizootics among the gerbilles will in this region be very considerably reduced, at any rate for a year or two, until the veld is replenished by the prolific habits of these animals. The field conditions of the epizootic were so suggestive of plague that at first the laboratory observers were unprepared to find a causative organism other than *B. pestis*. But all laboratory tests on numerous specimens from De Aar and neighbouring districts proved negative for plague. After the epizootic had lasted a month no progress towards discovering its cause had been made, except that it was fairly definitely not plague. Meanwhile the wide area over which rodents were dying was causing considerable local alarm, which the occurrence of two undoubted cases of human bubonic plague within the affected area tended to increase. Eventually the causative organism of at any rate part of the epizootic was proved to be a Pasteurella. This organism was frequently present, often in great numbers, in the blood and organs of animals found dead. By scarification with blood or organs from such animals other rodents sickened and died, presenting appearances identical with those of the animals found dead of the natural disease. The organism was also grown on laboratory media; inoculation or scarification of suitable rodents with the organism in pure culture reproduced the disease in a manner similar to that of animals infected by scarification directly from animals dead of the natural disease. Uncertainty whether this Pasteurella was responsible for the whole of the epizootic is caused by the fact that in many gerbilles examined the organism was not found; scarifications from such gerbilles were not fatal to others. Dr. Pirie of the South African Institute for Medical Research suggests that these gerbilles did die from the effects of the Pasteurella, but failed to show it because of a partial, though imperfect, immunity. The organism which is responsible then for part, if not all, of the epizootic is placed by its morphologic, biologic, and pathogenic characters among the Pasteurellae or haemorrhagic septicaemia group of bacteria. Should it prove to be a new species, Dr. Pirie suggests the name *Pasteurella desmodilli* as indicative of its origin from the Namaqua gerbille (*Desmodillus auricularis*). Meanwhile, isolated cases of human plague continue to occur. In the Government bulletin of April 13th four cases are reported from farms in various parts of the country—a European in the Hopetown district of the Cape Province, who was on trek when he contracted the disease; a native in the Bothaville district, Orange Free State; two other native cases (one fatal) in the Hoopstad and Vredefort districts of the Orange Free State. In the bulletin of April 20th a fatal case in a European schoolboy is reported from a farm near Parys. Government health and rodent officers are sent to investigate such outbreaks wherever they occur; these officers take all possible precautions to prevent the spread of the disease. Dr. Hauptfleisch, the district surgeon who was reported in the *British Medical Journal* of May 4th (p. 826) to have contracted bubonic plague, as the result of infection while making a post-mortem examination, has made a complete recovery.

Precautions Against Influenza.

With the advent of winter, health authorities are becoming alert to the possibility of the spread to South Africa of the influenza which has been prevalent in Europe and the United States of America. A number of cases have occurred on board vessels arriving at Union ports. These have been successfully dealt with up to the present, and no contact cases have occurred; but the precautions may not be adequate when colder weather renders the local population more susceptible. The Government Health Department has therefore issued a pamphlet on influenza to all local authorities and magistrates in the Union, so that they may be prepared to deal with any emergency that may arise. The pamphlet urges the usual precautions, such as avoidance of needless exposure, the necessity for stopping work and going to bed on the appearance of the very first symptoms, and the organization of local medical and nursing services. The advantage of forming a "pool" of unattached medical men is pointed out. Where there is a serious shortage of medical men the whole area affected may be divided up into suitable districts, equal in number to the medical men available. With one doctor allocated to each district, much time and unnecessary travelling in this country of vast distances will be saved. For meeting the often more serious problem of the shortage of nurses a similar subdivision of the area is recommended. The trained nurse in each district will serve as a nucleus round which a service of voluntary helpers can be gathered. The co-operation of the V.A.D., if locally organized, should be enlisted in carrying out any scheme of nursing. It is pointed out that measures may be taken which, in the aggregate, may reduce the opportunities of infection. By thus helping to prevent mass infection serious dislocation of the ordinary life of the community may be prevented; such dislocation itself increases the danger by making proper care of the sick difficult.

Immunization of Typhoid Contacts.

At its last meeting the Council of Public Health, established under the Public Health Act, 1919, discussed the great economic loss to the country resulting annually from typhoid fever. They recommended that prophylactic immunization of all contacts be carried out by local authorities immediately after the discovery of a single case, and they drew attention in this connexion to the advantages in certain circumstances of the oral method of immunization. The Secretary for Public Health has followed up the council's resolution by issuing a pamphlet on typhoid to all local authorities and magistrates in the Union. In the covering letter the advantages of the oral method of vaccine administration are indicated. It is mentioned that immunity appears to be established more quickly by the oral than by the injection method; many persons who would object to injections are willing to take medicine in pill or tablet form by the mouth. The vaccine is quite harmless, and may be taken by anyone; it is supplied together with ox-bile tablets, which aid its action; an ox-bile tablet is taken last thing at night, and a vaccine tablet first thing next morning, for three successive days. Tablets for oral administration are obtainable from the South African Institute for Medical Research, Johannesburg, and also from the Government Laboratories at Capetown and Durban. The cost to local authorities is 9d. per dose sufficient for one person—that is, three bile and three vaccine tablets. The Secretary for Public Health emphasizes the fact that immunization, whether by the oral or injection method, must not be regarded as a substitute for the sanitary measures required to prevent the occurrence and spread of typhoid infection. Immunization must be regarded as an immediate and supplementary precaution.

The Late Sir Thomas Smartt.

The career of Sir Thomas Smartt as a medical practitioner was brief, and the public of South Africa was hardly aware that his name was on the *Medical Register*. It is as a statesman that he will be remembered—as leader of the Opposition when the Botha Government was in power, and later (after General Smuts had succeeded General Botha as Premier and had formed a coalition with the Unionist Party) as a Cabinet Minister. Thomas Smartt was born in 1858 at Trim, County Meath, Ireland. Soon after his birth his widowed mother moved to Dublin, in which city he grew up. He received his medical education at Adelaide Hospital, qualifying as Licentiate of the College of Surgeons at the age of 19. He had to wait until his majority before his licentiateship could be registered, after which he went to Australia as ship surgeon. Some months later he landed in Capetown, and we find him on the Cape *Medical Register* in October, 1880. During the Basuto war of 1881 he served for some months as surgeon in Carrington's column. After that he commenced practice in the remote Karroo district of Britstown, of which he

was appointed district surgeon; it was here that he commenced farming, which in later life he carried on so successfully. What the inducement was to commence farming in that arid area is very difficult to imagine. His contribution to the development of South Africa as a scientific farmer is by some considered to be as valuable as his statesmanship. He commenced political life in 1891, relinquishing his district surgeoncy for the purpose. He entered the Cape Parliament in 1824 as member for Wodehouse, and sat in that and the Union Parliament almost continuously until his death last month.

Scotland.

Presentation to Sir Alfred Ewing.

SIR ALFRED EWING, F.R.S., and Lady Ewing are receiving many tokens of regard on the eve of the former's retirement from the position of Principal of Edinburgh University. In April the retiring Principal received the Freedom of the City of Edinburgh. On June 11th portraits of Sir Alfred in his robes as vice-chancellor, painted in oils by Mr. Henry Lintott, R.S.A., were presented to the University and to Lady Ewing at a large and representative gathering of subscribers. A letter of apology for absence was read from the Earl of Balfour, Chancellor of the University. Lord Provost Sir Alexander Stevenson, in presenting the portrait to the University, referred to the services of Sir Alfred Ewing to the State, outstanding among which was his work at the Admiralty during the war, and to the University, which he was leaving after a period of unexampled development and expansion. He was carrying with him into his retirement the affection and esteem of very many friends. Sir John Gilmour, the Lord Rector, accepted the portrait on behalf of the University. The Lord Provost then presented a smaller portrait of the Principal to Lady Ewing as a personal gift to herself from the subscribers. On June 14th Sir Alfred and Lady Ewing received parting gifts from the students at a great gathering in the McEwan Hall. Mr. D. E. Keir, senior president of the Students' Representative Council, and Miss C. Hogg, junior president, made the presentations. The Principal made a delightful and highly characteristic reply. Another honour which is about to be conferred on Sir Alfred Ewing is the degree of Doctor of Science of Oxford University. On June 22nd a reception is being held in the Old College, Edinburgh, to welcome Sir Thomas Holland, the new Principal, and Lady Holland.

University of Edinburgh Alumnus Association.

The annual general meeting of the University of Edinburgh Alumnus Association was held in the Senate Hall on June 13th. In the absence of the president, Mr. Alexander Miles, P.R.C.S.Ed., the chair was taken by Dr. Logan Turner. Reference was made to the loss the association had sustained through the death of the Hon. Lord Constable. It was reported that a branch of the association had recently been formed at Hull, and that one was in process of formation in South Wales. During the year donations were made from the funds of the association to the Women Students' Union for an "Alumnus Association Room" (£200), to the Athletic Club towards a new pavilion at Craiglockhart (£100), to the University Settlement (£50), to the Inter-Universities Students Representative Councils Conference, and to the University Fives Club for a cup for annual competition. On Armistice Day a wreath was laid on the University war memorial. A useful function of the association had been to provide members in different parts of the world with such technical information as was within the province of the University to supply. The annual reunion was to be held in the Women Students' Union on June 27th, the date of the Arts Graduation, and invitations would be issued to all the graduands, including the honorary graduands, and to all final-year students in the other faculties. Professor Hannay congratulated the convener of the editorial committee, Dr. Logan Turner, on the current issue of the association's magazine, the *University of Edinburgh Journal*, which contained, in addition to much University news, notable and finely illustrated articles on the University Raeburns by Mr. James L. Caw, and on Professor David Masson by his daughter, Miss Flora Masson. The chairman appealed for still further support for the association, which was amply justifying its existence as a means of contact between graduates all over the world and their University.

Matriculation of Edinburgh Medical Students.

The Edinburgh University Court has decided that from October, 1930, no student shall be permitted to enter on the medical curriculum until he has passed the pre-registration examinations in chemistry and physics. A tuition course in chemistry for the examination will be arranged during the long vacation. Hitherto students have been allowed to start the medical course without having passed the pre-registration examination, provided they attended classes in elementary chemistry and physics and appeared for the examination at the end of the first three months.

New Graduation Hall at St. Andrews.

The new graduation hall which has been presented to the University of St. Andrews by the generosity of Dr. James Younger, LL.D., and Mrs. Younger, has now been almost completed. The need for a building of this nature had long been felt. The final designs were made in 1923 by the late Paul Waterhouse, F.R.I.B.A. The great hall, rising to the full height, runs north and south to a depth of 190 ft., with its stage at the northern end; while at the southern end are grouped the main entrance, the vestibule, the foyer, from which rise the double staircases, the robing rooms, and the lounge. The façade at the southern end, on a frontage of 170 ft., forms a noble and dignified continuation to the other University buildings in North Street. A great portico, surmounted by a classic pediment, articulates the main form of the hall, and this is flanked on either side by the club rooms and robing rooms. These are connected to the central block by the bold sweep of the walls that contain the main staircase. Advantage has been taken of the natural fall of the ground to place a large supper room, seating 80 persons, under the stage, with easy access and good natural light. The whole of the external stonework, with the exception of the columns, entablature, and pediment of the south portico, is of Cullaloe stone of a deep buff tone from the quarries near Aberdour. The external carving was modelled and carried out by Mr. A. Carrick, A.R.S.A. The roofs are covered with red Lombardic tiles. The floor of the hall (exclusive of stage) seats 624, and the main gallery 436 persons. The decoration of the hall has been kept extremely simple, and depends for its effect on its proportions and the very fine quality of the woodwork in Italian walnut. Special care has been taken over the acoustic properties. It is hoped to use the hall for a variety of purposes—University graduations and ceremonies, speeches, orchestral performances, stage plays, dances, and examinations. The cost of the whole building and site is approximately £95,000.

Dundee Royal Infirmary.

The annual meeting of the governors of Dundee Royal Infirmary was held on June 10th. Mr. Francis Stevenson, the chairman, said he would again emphasize the great necessity there was for everyone taking to heart his or her responsibility for helping in the great work of healing carried on at the Infirmary. During the last ten years, while over £80,000 had been added to the endowment fund, the income of which could be used only for the purposes of the institution, it might surprise them to learn that in one year only had there been a surplus carried to the reserve fund, the fund available for the general purposes of the hospital. From that fund, which stood at £109,765 in 1918, and towards which £103,305 had been received during the intervening years, it had been found necessary to draw a total sum of £161,663 in order to meet annual deficits, leaving the amount of the fund at £51,467 at December 31st. Reference was made to the gift by Mr. James Prain of the house in Dudhope Terrace as a preliminary training house for nurses. The house was ideally

situated in close proximity to the hospital, and would accommodate a sister-in-charge and seven pupils, who would spend two or three months there before engaging in regular ward duties.

Gift for Aberdeen Nurses.

Viscountess Cowdray, who has made generous gifts to nursing institutions in London and elsewhere, has given additional proof of her good will towards the nursing service of the country, and more particularly to the nursing service in the North of Scotland, by presenting the title-deeds of the Viscountess Cowdray College of Nursing Club to the Aberdeen branch of the College of Nursing—a gift representing more than £20,000 in terms of money. It is understood that this gift is associated with the thanksgiving movement for the King's recovery. It will be recalled that Lady Cowdray and the late Viscount Cowdray gave £25,000 each to initiate Lord Provost Lewis's Aberdeen Joint Hospitals Scheme, for which £408,000 has been raised in a couple of years. These are only some of the Cowdray benefactions to the city.

England and Wales.

Harveian Society.

THERE was a very large attendance of Fellows and visitors at the annual dinner of the Harveian Society of London, held at the Connaught Rooms on June 13th, with the president, Mr. Duncan C. L. Fitzwilliams, in the chair. All those present on this occasion were the guests of one member, Mr. George Buckston Browne, who has generously created a trust for the endowment of the society's annual dinners. After the loyal toasts had been honoured, Sir D'Arcy Power proposed the health of the Harveian Society, and the president, in replying, paid a tribute to the work of Sir D'Arcy—himself a past-president—to Mr. Buckston Browne, and to the officers of the society, whose efforts had contributed so much to its present prosperity. Dr. J. Walter Carr, president of the Medical Society of London, Lieut.-Colonel C. T. Samman, Master of the Apothecaries' Society, and Mr. A. P. Herbert of *Punch* replied to the toast of the visitors, which had been proposed by Dr. R. Cove-Smith.

National Association for Prevention of Tuberculosis.

The fifteenth annual conference of the National Association for the Prevention of Tuberculosis is to be held at Newcastle-upon-Tyne from October 10th to 12th. The chairmen are to be Sir Robert Philip and the Hon. Sir Arthur Stanley, and the principal subjects set down for discussion are "The factors that produce adult pulmonary tuberculosis," to be introduced by Dr. Edouard Rist of Paris, "National propaganda regarding tuberculosis," "Combined treatment and technical education of tuberculous youths," and, at a professional meeting, "The teaching of tuberculosis to undergraduates" and "The training of tuberculosis medical officers." An address is also to be given on "Tuberculosis on Tyneside," to be followed by discussion. Among those who are announced to take part in the proceedings of the conference are Sir Thomas Oliver, Professor Thomas Beattie, Dr. Fergus Hewart, Dr. W. H. Dickinson, Mr. William Guy (who is to speak on the relation of dentistry to the subject), Dr. A. H. Macpherson, medical superintendent of Burrow Hill sanatorium colony, and Dr. William Brand and Dr. Harley Williams, respectively senior and assistant medical commissioner to the National Association. The conference is open to all persons interested in tuberculosis on the payment of a fee of one guinea, and the Ministry of Health sanctions the payment of expenses of representatives by county and county borough councils and other authorities. The National Association has issued a report on the result of its recent special appeal for £100,000. The result, as announced some time ago in these columns, was that a larger sum than asked for was obtained. An amount of £59,684 was raised as a result of various efforts, to which an anonymous donor added a gift of £50,000. The money is being spent in education (for which purpose four highly qualified medical men have been engaged as lecturers), in the establishment of care committees for the supervision of patients and their families, in grants towards workshops for tuberculous patients, in assistance to the Burrow Hill colony, which is an experimental scheme for providing treatment and training for lads, and, finally, in helping individual cases where the official tuberculosis machinery does not cover the particular need.

Electric Supply in a Mental Hospital.

On October 5th, 1928, the Commissioners of the Board of Control, following their inspection of the County and City of Worcester Mental Hospital at Powick, directed attention to the benefits that would accrue to the institution from the installation of an electric supply. Much of the dinginess they noted was attributable to the use of an inadequate illuminant, and in the absence of electricity a number of suggestions they would wish to have made had to be deferred. The Commissioners expressed the hope, however, that as soon as the electric light was available no time would be lost in providing the hospital with a cinema apparatus, which their experience taught them was so much appreciated in mental institutions elsewhere. It is gratifying to note that, in his report for 1928–29, the medical officer and superintendent, Dr. H. F. Fenton, was able to state that the question of the introduction of electricity into the hospital was under immediate consideration by the committee. Besides the many purposes for which electricity could be used in the various departments of the hospital, it had, he pointed out, the advantages of affording increased safety, better health conditions and facilities for treatment, and greater comfort to the patients.

Correspondence.

PREVENTION OF MENTAL DISORDER.

SIR,—The National Council for Mental Hygiene earnestly wishes to draw attention to the urgent need for improved facilities for the treatment of poor persons suffering from nervous or mental breakdown, of a type which does not constitute insanity. They form a large class for whom little or no provision at present exists; yet the conditions from which they suffer are responsible for a large amount of avoidable invalidism and inefficiency as well as mental distress. For the rich who suffer in this way there are medical specialists and nursing homes available. For the poor there is practically no provision.

In England and Wales two special hospitals—the Lady Chichester Hospital at Hove and the Maudsley Hospital in London—provide beds for such patients; but only one or two out of the large number of general hospitals make any special provision, and then only to a meagre extent. Yet the functional nervous types of illness are numerically as frequent as any. Poor patients have, therefore, usually to be sent, if they are placed in hospital at all, to the observation wards of Poor Law infirmaries, where all kinds of mental illness are nursed in the same ward. This is detrimental to patients whose illness is of the variety referred to. Not, in fact, until the extreme stage of certifiable insanity is reached, when the patient is removed to a mental hospital, does any adequate treatment become available. Much more commonly the patient drifts helplessly, unhappy and inefficient, and often completely incapable of work for a period that has no definite limit. Apart from the suffering and unhappiness involved, the economic wastage of time and money is incalculable.

In reference both to this class of case and to the other and usually more severe types of mental illness, the Report of the Royal Commission on Lunacy and Mental Disorder, published in 1926, formulates the following principles:

"1. Illness of the mind should be regarded as an illness like other illnesses.

"2. The keynote of the future should be prevention and treatment.

"3. There is no clear demarcation between mental and physical illness. There are many cases of illness in which it is a question whether the physical or mental symptoms predominate.

"4. There is no definite line between the sane and the insane. It is a matter of degree. The degrees of mental instability are infinite.

"5. The number of persons who could avoid certification altogether would undoubtedly be increased if greater facilities existed for those who are willing to submit themselves to treatment.

"6. Hence the necessity of making provision in connexion with existing institutions or by the provision of new institutions for the treatment of mental disease from the very earliest moment of the appearance of its symptoms."

The report further states:

"In the case of every other type of institution for the treatment of disease the aim is to get into touch with the patient at the earliest possible stage of his attack and to ward off, or at least mitigate, its effects. Not so with the case of mental illness. Contrary to the accepted canons of preventive medicine, the patient who is becoming mentally ill is not admitted or admissible to most of the institutions provided for his treatment until the disease has progressed so far that he has become a certifiable lunatic. Then, and then only, is he eligible for treatment."

It is important to distinguish clearly between mental illness and mental defect. Mental defect is a failure of mental development, and is incurable. Nervous and mental breakdowns are illnesses which are often preventable and, in many cases, curable. They affect all classes, and frequently occur in persons of more than average mentality and usefulness. We are strongly of the opinion that accommodation and treatment for these cases will always be required in the ordinary public or municipal hospital, in addition to any provision which may be made for more established cases in special hospitals.

The new Local Government Act will inevitably involve a recasting of the whole public service. No scheme that is drawn up can be regarded as adequate which does not take into account the needs of those suffering from nervous breakdown and the early symptoms of mental illness. The National Council for Mental Hygiene sincerely hopes that public authorities will give their most earnest consideration to this question when submitting their schemes to the Ministry in regard to the administration of the new Local Government Act.—I am, etc.,

MAURICE CRAIG,
Chairman.

London, S.W.1, June 6th.

DEATH AFTER AVERTIN ANAESTHESIA.

SIR,—We think that the following report of a fatality following avertin anaesthesia may be of interest, as it resembles somewhat a case recorded by Dr. Blomfield and Sir F. E. Shipway in the *Lancet* of March 16th last.

The patient, a young and apparently healthy adult, was admitted to hospital on June 10th suffering from a right inguinal hernia. No sign of disease could be detected in the heart, lungs, or kidneys. He had the customary preparation—that is, a laxative on the evening of the operation and simple rectal washouts the following morning. At 5.30 p.m. his blood pressure was 125 mm. Hg, and morphine hydrochloride gr. 1/4 was given. The dose of avertin given was 5 c.cm. in a 3 per cent. solution, which was rather less than 0.1 gram per kg.; this was given at 6 p.m. It had been intended to supplement this with intrathecal novocain or gas and oxygen.

At 6.30 p.m. the operation was commenced. It was found that the anaesthesia was deeper than we desired for combination with spinal novocain, but not sufficiently deep for the operation to be carried out. The patient was somewhat cyanosed, but after the administration of a little gas and oxygen the colour rapidly became satisfactory. The operation was concluded at 7 p.m., and no anxiety was felt with regard to the patient's condition. During the operation his blood pressure was again taken and found to be 118 mm. Hg.

At 9.30 p.m. the patient was a little cyanosed, but respirations were regular in frequency and depth, and the volume of the pulse was excellent. Consciousness had not been regained. At 12 midnight cyanosis was more marked, and the pulse commenced to fail. Artificial respiration was resorted to, strychnine was given, and, finally, intracardiac adrenaline. In spite of all efforts the patient died.

A post-mortem examination was made by Dr. Stuart McAusland, lecturer in anaesthetics, David Lewis Northern Hospital, Liverpool. He reported the presence of a thymus gland weighing slightly more than 1/2 ounce, slight congestion of the lungs and brain, normal appearance of the rectum and other organs.

The conclusion which we draw from this case is that this man failed to eliminate the drug. The method of fractional administration as approved by Mr. Morrin would not have aided us, as our patient actually had less avertin than he advises for the initial dose. We must add that the drug has given very satisfactory results in all the cases in which it has been used previously in this hospital.—We are, etc.,

HENRY H. MACWILLIAM,
Medical Officer,
A. K. WILSON,
Senior Resident Medical Officer,
Walton Infirmary, Liverpool.

Liverpool, June 17th.

SUBARACHNOID ANEURYSM.

SIR,—Dr. M. C. Andrews's interesting case of ruptured subarachnoid aneurysm, reported in the *Journal* of June 15th (p. 1075), induces me to call attention to a case which I reported in 1925.[1] So far as I know, it is the only case on record in which an aneurysm of the basal arteries which had not ruptured or leaked has been diagnosed during life and confirmed at a subsequent necropsy.

Briefly, it is the case of a man, admitted to St. Bartholomew's Hospital under the care of Sir Thomas Horder, who was ultimately proved to be suffering from infective endocarditis, of which he died. Suddenly one night he developed a severe headache, and went blind in his right eye. The pupil of this eye reacted briskly to consensual light stimulus, but was quite inactive to direct light stimulus. There was nothing in the fundus to account for any loss of sight, and he stated that the sight of the other eye was perfect. (Later this proved to be not quite correct.) It was clear, therefore, that there was complete interruption of conduction somewhere between the back of the globe and the front of the chiasm on the right side, and in the absence of injury or any reason to suspect a metastatic malignant deposit, I wrote: " . . . is it possible that there is a localized aneurysm pressing on the optic nerve?" At the post-mortem examination seven weeks later a small unruptured and unleaking aneurysm about the size of a cherry was found, apparently at the termination of the internal carotid, on the right side, which had torn completely across the optic nerve. The specimen is in the museum of St. Bartholomew's Hospital, No. 2553A.—I am, etc.,

R. FOSTER MOORE.

London, W.1, June 15th.

SPA TREATMENT.

SIR,—As the date of the annual conference of the Spa Practitioners Group of the British Medical Association is drawing near it would be helpful if members intending to be present would give previous thought to the wording of a definition of a spa and of spa treatment. The definition used at the last meeting was approximately as follows:

"Spa treatment is treatment at a place possessing natural mineral waters of known therapeutic value and facilities for their application. This implies the existence of bath-houses, apparatus, and trained personnel for work in bath-houses and other physiotherapeutic departments. However great the importance of auxiliary treatments may be, drinking and bathing in fresh natural mineral waters form the basis of all genuine spa treatment."

As I drafted the foregoing definition for the purpose of a meeting at the British Medical Association House in connexion with the proposed spa treatment of insured persons, I was much interested in the criticisms it received at the subsequent Annual Meeting of the British Medical Association. I was not able to attend the meeting, but from the report in the *British Medical Journal* it seemed that certain critics feared that "mineral waters" would be interpreted as drinks of the ginger beer and lemonade variety. Perhaps they were being facetious, but it may be admitted that the word "mineral" is not essential. That particular phrase would thus read "fresh natural waters." The term "fresh natural waters" implies waters of either high or low mineralization when used at their source, and in this connexion is employed as distinctive from sea water and drinking water, the so-called tap water of common domestic use. It was evident that some of the

[1] *Trans. Ophthal. Soc. of the United Kingdom*, 1925, xlv, Part ii, p. 492.

criticism of the original definition came from representatives of certain seaside health resorts, which they were anxious to have included in the list of "spas."

The term "spa," taken from the Belgian health resort of that name, has by usage and common consent, both in this country and abroad, hitherto been limited to health resorts possessing natural waters with special therapeutic properties, but spas have never been confused with marine health resorts. The value of marine health resorts is quite as well known as, and in this country much more widely known than, the value of the spas. The presence of waters of the type under discussion at a seaside resort would, with the provision of facilities for their use, entitle it to rank as a spa, but mere proximity to sea water certainly does not do so.

Another objection was to the phrase "known therapeutic value." All water properly applied has therapeutic value; but it is certain that it has been the discovery that natural waters—that is, waters as they occur in nature—in certain localities possess distinctive therapeutic value which has led to the establishment of spas in these localities, after these special therapeutic properties have become known.

I would therefore suggest the following wording of the definition:

"Spa treatment is treatment at a place possessing natural waters of distinctive therapeutic value and facilities for their application. This implies the existence of bath-houses, apparatus, and trained personnel for work in bath-houses and other physiotherapeutic departments. Drinking and bathing in such fresh natural waters form the basis of all genuine spa treatment. The term fresh natural waters includes waters of either high or low mineralization when used at their source, but in this connexion is employed as distinctive from sea water and sweet drinking water, the so-called tap water of common domestic use."

—I am, etc.,

Harrogate, June 17th. GEOFFREY HOLMES.

SIR,—My attention has been drawn to an article by Dr. W. Edgecombe of Harrogate which appeared in the *British Medical Journal* of June 1st (p. 981). He states that the only example of waters containing bromine and iodine in Great Britain is "the water of Woodhall Spa." He evidently has not seen a recent analysis of Bridge of Allan waters. Their most important constituents are the chlorides of sodium, calcium, and magnesium. The chloride of calcium is present in quantities unusual to find in mineral waters either at home or abroad. They also contain bromine and iodine.

Bridge of Allan was at one time a famous spa, with mineral waters that were celebrated all over the world. Its decline began about the year 1890. Other British spas about that time were introducing Continental methods of treatment, but Bridge of Allan did nothing to bring it into line with the requirements of the day, and the inevitable followed. It is only a spa in a secondary sense at present, and if the town council wish to restore prosperity to the place it will be necessary to modernize its spa.

Dr. Fortescue Fox, who visited Bridge of Allan in 1922 and reported on the waters, bath establishment, etc., said: "Bridge of Allan, if scientifically developed, will take a distinct and definite place among British spas. . . . I entertain no doubt that the resources of Bridge of Allan are sufficient for a first-rate spa." He concludes his report by making a suggestion that a syndicate might develop the spa on modern lines, if the town council are disinclined to undertake the work.—I am, etc.,

J. HOSACK FRASER, M.B., F.R.C.P.Ed.

Bridge of Allan, June 13th.

SIR,—I have read Dr. Wilfrid Edgecombe's article (June 1st, p. 981) with much interest, and am in entire agreement with many of his conclusions concerning mineral waters and the exploitation of spas. I believe, however, that his classification of mineral waters according to their chemical constitution in the face of recent advances in medical hydrology (due largely to such pioneers as Fox and Ray in England) is not altogether justifiable. The chemical constitution, as considered in the past, does not represent everything, for it is but a medicament of a complex nature, with certain tangible and immediate effects (catharsis, diuresis, etc.), which must not be considered apart from certain very important physical and biological properties such as osmotic action, electrical reactions, and radio-activity. Indeed, it is likely that in the near future electrical conductivity depending on the number of free ions will be taken as a classification of mineral waters, for the study of waters at the present time is, beyond doubt, passing beyond chemical data to their physical and biological properties, and although such investigations are still in their infancy there are already opening up horizons on their mode of action on the body. As bearing on this important point it may be useful to remark that waters, although of different chemical composition, may have similar effects, and conversely; and again, that not infrequently slightly mineralized waters are very potent therapeutically. Again, as regards "specific actions" claimed by certain spas, there may be grounds for disagreement with Dr. Edgecombe's contention. Take, for instance, the specific actions justly claimed for the sulphur waters of Harrogate in certain affections, for Châtel Guyon in colitis, for Bad Nauheim in cardiac troubles, and for Montecatini in affections of the liver and gall-bladder.—I am, etc.,

Montecatini, June 3rd. T. GERALD GARRY, M.D.

THE DEFINITION OF RHEUMATOID ARTHRITIS.

SIR,—In reply to Dr. M. B. Ray's communication (June 15th, p. 1098), I hope I made it clear, in my article published in your previous issue, that I regarded rheumatoid arthritis as an entity quite distinct from infective and osteo-arthritis. My introductory remarks were made with this aim in view. On the other hand, I think Dr. Ray's proposal that the term "rheumatoid arthritis" should be confined to a disease occurring exclusively in women is too drastic. I am convinced that the condition is met with, though rarely, in young males, and is of different nature from that of infective or focal arthritis. The term "atrophic" may be used vicariously with that of "rheumatoid" for this disease.—I am, etc.,

London, W.1, June 15th. A. H. DOUTHWAITE.

IMMUNIZATION BY TUBERCULIN.

SIR,—Dr. Nathan Raw's paper on the production of immunity to tuberculosis (May 25th, p. 950) opens up a subject of enthralling interest. Most of us will think that living cultures of tubercle bacillus should not be used for the purpose. This bacterium is of such toughness that to entrust it, in the living state, to the human tissues, *seems* risking the possibility of reactivation. Tuberculin, it must be granted, can, by dosage, deal out stimulating taps or staggering blows. But, like a certain two-handed engine of old, it stands only to strike once, and strike no more. Now it can be foreseen clearly that, ere long, the real worth of tuberculin, both for treatment and for immunizing, must become generally recognized.

Dr. Nathan Raw rightly says that "all cases of tuberculosis" (assuming them, of course, to be uncomplicated) "should be treated by some form of tuberculin, which is the natural specific remedy." But I cannot follow him when he says, "this tuberculin should be prepared from attenuated, avirulent, non-toxic cultures," and that "attenuated cultures retain the quality of producing tuberculin, and, being deprived of their virulence and toxicity, are perfectly safe in use."

But what is tuberculin if not a toxin, the natural weapon of the organism? Of what use is any vaccine without its specific toxin? Toxicity is, moreover, a relative term, and toxins, when sufficiently diluted, become useful in therapy. Thus we start by giving very small doses of P.T.O. in lupus, where tuberculin sensitiveness is acute, and where focal reactions are easily observed. But the amount that causes reaction at first, fails to do so if repeated several times, and appreciably more must be given if the same result is to be again brought about. This judicious pushing of the dose constitutes the safest,

and surest, method of obtaining immunity. Nothing of a lasting nature could be produced, or even expected, if only weak dilutions were administered. It takes strong tuberculin, rightly timed, to make strong immunity, and it is only when pulmonary cases get up to P.T. that most of them begin to assume their former vigour; then it is that fibrosis becomes most definitely established, and cough and sputum tend to cease altogether.

If it can be shown that it is possible in cases definitely infected to stem, and finally to oust, the disease, is it not reasonable to infer that merely suspected cases can also be immunized, and with very much less difficulty? I refer, of course, to persons with family diathesis, to contacts, who are to some extent test-sensitive, to all, in short, who have come within the shadow of this devastating scourge. We can immunize these cases easily, no less thoroughly than the rest, and the sooner this is done the better. Children and young people, by their easy tolerance of, and ready response to, tuberculin, are especially fitted to be thus safeguarded, and, taking a long view, it looks as if this were the right end at which to begin. I believe that if this course were generally adopted acute pulmonary tuberculosis would become rare. Naturally we do not know everything about the subject, and many of the gaps in our knowledge will probably take years to fill; but we have gained enough, from reason and experience, to make a start, and to go forward boldly with the greatest hope.—I am, etc.,

Weymouth, June 12th. H. C. MANNING.

Obituary.

SIR WILLIAM J. THOMPSON, M.D., F.R.C.P.I.,

Formerly Registrar-General for Ireland.

As briefly announced in our last issue, Sir William J. Thompson, M.D., late Registrar-General for Ireland, died suddenly on the night of Sunday, June 9th, at his residence in Fitzwilliam Square, Dublin, at the age of 69 years.

The news of Sir William Thompson's death has come as a shock to his many friends, who held him in sincere affection, and to the general community in Ireland, to whom he was well known by reputation. Only three days before his death he had attended the General Assembly of the Presbyterian Church in Ireland as lay member of a deputation from the Methodist Conference, and had delivered a speech welcoming the Assembly to Dublin. On June 9th he attended both services at the Methodist Centenary Church in St. Stephen's Green. In the afternoon he visited the Peamount Sanatorium, in which he had taken the warmest interest since its foundation; he remained chairman of its committee or management until the end. On that Sunday evening he had a few intimate friends to dinner, and appeared to be in his usual health; a few hours afterwards he passed quietly away in his sleep.

William John Thompson was born in 1861 at Cavanaleck, County Tyrone, but his entire life since he was a student had been spent in Dublin. He followed a distinguished professional course of studies at the Royal College of Surgeons and at Trinity College, graduating B.A. of the University of Dublin in 1892, M.B. in 1894, and proceeding to the Doctorate of Medicine in 1895. He obtained the diploma of L.R.C.P.I. in 1888, the M.R.C.P. in 1893, and the F.R.C.P. in 1902. Soon after qualification he was elected demonstrator of anatomy to the College of Surgeons, and was appointed house-physician in St. Vincent's Hospital. He later became a visiting physician and, finally, senior physician to Jervis Street Hospital. He was a Past-President of the College of Physicians, and a Fellow of the Royal Academy of Medicine in Ireland, and had held the position of president of the Leinster Branch of the British Medical Association. A special share of his professional skill and energies was devoted to combating tuberculosis and infantile diseases. In the anti-tuberculosis campaign in Ireland he was a conspicuous figure, and became consulting physician to the National Hospital for Consumptives.

During Lord Aberdeen's tenure of the Viceroyalty in Ireland William Thompson was Physician-in-Ordinary to the Lord-Lieutenant, and he received the honour of knighthood in 1907. He was closely identified with all of Lady Aberdeen's activities in promoting a better condition of public health, notably with the supply of pure milk to children. Even after he became Registrar-General in 1909, he found an opportunity in the census returns of fixing public attention on the two causes, which he had made particularly his own. He retired from this office in 1926, when the statistical administration was entirely recast. Apart from his manifold public duties, a word must be said about another aspect of the man. There were those who knew him as a devoted and efficient practitioner in private cases. Unsparing of himself, he combined professional skill with a kindness and modesty of manner which sought to obscure it, and established a lasting claim on the regard of his patients and their friends. In social life he was held in universal esteem.

We are indebted to Professor T. GILLMAN MOORHEAD for the following tribute:

During the last five years I have been closely associated with the late Sir William J. Thompson on hospital and other committees, and desire to pay a brief tribute to him as a loyal friend and colleague. In all his work Sir William Thompson showed an intense anxiety for the welfare of the particular institution with which he was dealing, and took infinite trouble over details which, though necessary, were often uninteresting. He was a most useful individual in this respect, for he cheerfully and willingly undertook work which others were inclined to leave either undone or to be done by paid officials. In all this he was never self-seeking, and more than once allowed others to gain the credit for what he had himself accomplished. He was a man of peace, and helped on many occasions to conciliate conflicting interests and to bring in an element of calmness and of judgement on matters of contention. Even before his retirement from the post of Registrar-General he had given much time to the services of charitable institutions. During the last three years these services were multiplied, so that he spent the greater part of each day in work of that kind. His loss as a friend and helper will be deeply mourned by many. He was a true gentleman.

JOHN HEDLEY MARSH, M.R.C.S.,

Past-President, Lancashire and Cheshire Branch, British Medical Association.

WE regret to record the death, in his sixtieth year, of Dr. J. H. Marsh, which took place suddenly on June 6th, at a nursing home in Buxton.

John Hedley Marsh was educated at Owens College, Manchester, and in 1894 obtained the diplomas M.R.C.S., L.R.C.P. After holding appointments as senior house-surgeon at Macclesfield General Infirmary and the Manchester Royal Infirmary, he engaged in general practice, and actively identified himself with the work of the British Medical Association. From 1914 onward he was a member of the Lancashire and Cheshire Branch Council, being elected its president in June, 1923; he was also vice-chairman of the Stockport Division from 1915 to 1916, chairman from 1917 to 1923, and a member of its executive committee from 1924. In 1916 and 1927 he represented his Division in the Representative Body of the Association, and in 1928 was a member of the Insurance Acts Committee. In the course of his professional work in Macclesfield Dr. Marsh held appointments as honorary surgeon to the General Infirmary; medical superintendent to the Isolation Hospital; surgeon to the county police; school medical officer, and medical officer of health. He was made chairman of the County Palatine of Chester Local Medical and Panel Committees in 1917, having previously held office as vice-chairman during the chairmanship of Dr. T. W. H. Garstang. In recognition of what his fellow practitioners described as "spirited leadership" and of "a decade of genial and judicious conduct in the chair," the members and constituents of the local medical and panel committees presented Dr. Marsh, in 1927, with a bookcase bearing an illuminated inscription. In spite of the demands of a large private and panel practice, of his medical appointments, and of the numerous committees of

which he was a member, he carried out conscientiously his duties as a justice of the peace. He was honorary life member and examiner to the St. John Ambulance Association, and a Fellow of the Royal Institute of Public Health.

We are indebted to Dr. LIONEL PICTON for the following personal tribute:

I first knew him when he was established at Macclesfield—at the zenith of his vigour and labour. We met on the local Medical Committee, new-formed to watch the Insurance Bill. Later, when that committee was recognized as statutory, Dr. Marsh was one of the leading members. He saw clearly that the profession must work through these committees if it was to save general practice. To do that was his objective. He viewed medicine as a whole. Good surgeon as he was, he was a doctor first. M.O.H. as he was, he was a G.P. first. His was a life amazing full! And he focused all his varied experience upon the problems before the Panel Committee. I knew him then as a fighter, tenacious, resourceful, replete with information, direct in his method, not *rusé*. Direct though he was, he saw where action led. His aim was to safeguard the G.P. in his freedom to practise. Every move he urged had that in view. He was very English in his outlook. A scheme remote from actuality did not interest him. His interest was in the next business.

He was marked out for chairman on Dr. Garstang's retirement, and was elected without question. For twelve years he held the office, and last year we thanked him for his services by a presentation. He was ill at the time and could not be present, but never was a tribute more sincerely rendered. The actual tokens were a bookcase, an address, and a chair. The *bookcase*, for he was a tremendous and rapid reader, medical works mostly—half Lewis's shop seemed to overflow his shelves, not to speak of mastoids and models. But he had wider interests. His alert mind shone into many portals. Of one he seldom gave a hint, but the volumes, recent and read, gave it, volumes on a certain broad, open-eyed school of divinity. Whatever else he read, for half an hour last thing at night a favourite technical book generally occupied him—Beesley and Johnston's "Surgical Anatomy." Four days before he died he said "Send me my bible" (as he called it). He wanted to look up the innervation of the stomach. It was his conviction that if the G.P. is to survive he must justify himself by precise and ready knowledge—up to date and constantly reviewed. For the doctor who had relaxed he had a humorous contempt: "a bismuth and tinct. camph. co. doctor" he called him. The *address* we gave him had unconventional illuminations; bismuth and tinct. camph. co. bottles occupied a lowly place in the design. The *chair* was because "the flesh is weak," as he used to quote. He had a long weakening illness that year. None the less his spirit drove him again into active work. It was *in* him and must out.

Here is an instance of his humorous method. In a debate on the county tuberculosis scheme and the changes the Panel Committee wanted, he suddenly seemed metamorphosed. He began to say the Ministry would require this, the Regulations would require that, and that these requirements would conflict with what the Panel Committee wanted. Up rose Sir William Hodgson to warmly defend the proposals. Most ably he did it. Thereupon Dr. Marsh, smiling, explained that his opposition was merely academic, and he congratulated himself on having drawn from Sir William a defence of the policy "with every word of which I agree." He was a chairman to be beloved—he was beloved, not as chairman only, but as a doctor and as a friend.

Dr. WILLIAM DOYLE, who died recently at Colne, in Lancashire, aged 59, was the son of the late Dr. Edward Doyle of that town. He was educated at the University of Glasgow, where he graduated M.B., C.M. in 1891. After a period in private practice with his brother at Leigh he became medical officer of health and school medical officer for Colne. During the great war he served as a temporary lieutenant R.A.M.C. in Gallipoli and Egypt, and subsequently at the Whalley Military Hospital. He was a member of the Burnley Division of the British Medical Association and a fellow of the Society of Medical Officers of Health. The funeral was attended by representatives of the numerous bodies with which he was associated.

The Services.

TERRITORIAL ARMY AMBULANCE CHALLENGE SHIELD.

ON June 8th nine medical units competed for the Territorial Army Ambulance Challenge Shield at the Duke of York's Headquarters, Chelsea. The shield was again won, for the second year in succession, by the 167th (City of London) Field Ambulance, who gained 333 marks out of a possible 400. The Runners-up Cup, presented by Lieut.-General Sir Matthew H. G. Fell, Director-General Army Medical Services, was won by the 170th Cavalry Field Ambulance with a total of 314 marks. The Director-General, when presenting the badges to the winners, remarked that the standard of all the competing teams was higher than hitherto, and this went to show how hard they had all worked to fit themselves for the competition. The shield will be presented to the winners at a future date by the Lord Mayor of London.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on June 14th the following medical degrees were conferred:

M.B., B.CHIR.—J. M. Lees, J. R. Armstrong, H. Scudamore, C. W. Shaw, R. Hodkinson.
B.CHIR.—G. W. Willcox.

At a congregation held on June 18th the following medical degrees were conferred:

M.CHIR.—R. H. Metcalfe.
B.CHIR.—E. J. Pye-Smith.

UNIVERSITY OF LONDON.

THE degree of D.Sc. in Biochemistry has been conferred on Mr. H. J. Channon for his thesis on the unsaponifiable fraction of liver oils, and that of D.Sc. in Statistics on Miss E. M. Newbold for her thesis on practical applications of the statistics of repeated events, particularly to industrial accidents.

Dr. A. M. H. Gray and Professor William Wright have been elected the representatives of the medical schools on the newly constituted Senate of the University. As announced in our issue of May 25th the representatives of the Faculty of Medicine are Lord Dawson of Penn, Mr. H. L. Eason, and Sir Cuthbert Wallace.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B., PART I (*in Forensic Medicine and Toxicology only*).—A. J. B. Miall, H. M. Strover, W. L. Sleight. PART II.—*R. A. S. Cory (with distinction in Pathology, Medicine, and Obstetrics), *R. J. Krogh (with distinction in Medicine and Obstetrics), Isabella J. Armstrong, A. C. Fisher, April Doreen James (with distinction in Public Health). *Group II (completing examination)*: E. Southam. *Group I*: N. D. Gerrish, Mabel F. Potter. *Group II*: N. L. Price.

* With second-class honours.

UNIVERSITY OF MANCHESTER.

DR. F. E. TYLECOTE, honorary physician to the Manchester Royal Infirmary, has been appointed professor of systematic medicine as from September 29th, 1929. He has been a lecturer in clinical medicine in the University since 1916.

UNIVERSITY OF SHEFFIELD.

MR. J. H. COBB, M.B., B.S., F.R.C.S., has been appointed lecturer on applied aural anatomy, and Mr. E. G. Mackie, M.B., Ch.B., D.O.M.S., lecturer on applied ophthalmic anatomy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting of the Royal College of Surgeons of England was held on June 13th, when the President, Lord Moynihan, was in the chair.

Fellowship.

Mr. Comyns Berkeley was introduced and admitted a Fellow of the College.

It was reported that of the 103 candidates who had presented themselves for the Fellowship examination 31 were successful, including 3 candidates who had not yet complied with the regulations. The Diploma of Fellowship was granted to the following 28 candidates:

C. D. Shapland, N. L. White, J. C. Ainsworth-Davis, R. C. Taylor, E. S. Freshman, L. N. Pyrah, J. V. O'Sullivan, A. M. Lazarus, R. M. Bates, A. Simpson-Smith, R. V. Cooke, H. P. Nelson, J. F. Simpson, N. Attygalle, H. J. Burrows, G. M. Fitzgibbon, V. Kathirgamatamby, A. K. Gupta, R. W. Kenney, F. J. Milward, N. M. Matheson, R. L. Flett, S. Howard, M. Axford, H. S. Billcliff, J. H. Cramsie, D. D. McKenzie, F. E. Stabler.

Membership.

The diploma of Membership was conferred upon Nancy M. Badeley, S. T. Crowther, Catherine Day, Margaret L. Hamburger, and T. Nallainathan.

Diploma in Public Health.

Diplomas in Public Health were granted, jointly with the Royal College of Physicians, to the following 25 successful candidates:

A. Bakhsh, Y. B. Bedi, F. G. Brown, J. P. Chaudhuri, D. S. Chowdhary, G. Covell, S. D. De Vos, H. N. Dewan, D. P. Dutta, Nancy G. Howell, B. S. Kanga, G. R. Lynn, Elsie Lyon, D. G. Mohile, S. Mufty, C. C. Po, Marion Ravell, A. L. Schokman, A. Sharma, Patricia H. S. Shaw, K. A. Soutar, H. S. C. Starkey, G. G. Stewart, K. M. R. Swami, J. P. R. Tennekoon, R. L. Tull.

Mr. McAdam Eccles was appointed a representative of the College to serve on the Executive Committee of the British Social Hygiene Council, in place of the late Sir Anthony Bowlby.

A letter from the chairman of the Lister Medal Committee was read reporting that the Lister Medal for 1930 for distinguished contributions to surgical science, with the honorarium of £500, had been awarded to Dr. Harvey Cushing of Boston, U.S.A. Dr. Cushing will give an address at the Royal College of Surgeons in 1930 on some date to be arranged later.

The President reported that the Sir Gilbert Blane Gold Medal for 1929 had been awarded to Surgeon Lieut.-Commander Thomas Norman D'Arcy, Royal Naval Promotion Examination, 1929.

The following examiners were elected for the ensuing year:

Dental Surgery (Surgical Section). L. B. Rawlins, H. S. Clogg, T. P. Legg, R. J. Howard, G. E. O. Williams, J. Murray, Sir Cuthbert S. Wallace, C. E. Shattock. *Fellowship (Anatomy):* C. P. G. Wakeley, P. N. B. Odgers, W. Wright, J. E. S. Frazer. *(Physiology).* H. E. Roaf, C. A. L. Evans, R. J. S. McDowall, J. Mellanby.

Under the Conjoint Examining Board:

Elementary Biology.—T. W. Shore, J. P. Hill. *Anatomy:* J. B. Hume, W. Wright, R. B. Green. *Physiology:* E. B. Verney, H. Hartridge. *Midwifery:* C. White, T. B. Davies, A. W. Bourne, S. Ferdike. *Diploma in Public Health:* C. W. Hutt. *Diploma in Tropical Medicine and Hygiene (Pathology and Tropical Medicine).* W. P. MacArthur; *(Tropical Medicine and Surgery).* P. H. Manson-Bahr. *Diploma in Ophthalmic Medicine and Surgery (Part I).* C. B. Goulden, H. W. Lyle. *(Part II).* R. A. Greeves. *Diploma in Psychological Medicine:* F. L. Golla. *Diploma in Laryngology and Otology (Part I):* W. M. Mollison, N. Patterson; *(Part II).* W. G. Howarth.

Primary Fellowship.

At the recent primary examination for the Fellowship 164 candidates presented themselves, of whom the following 47 were approved:

A. H. Baker, D. S. M. Barlow, A. W. Bayley, K. B. Bridge, E. Carew-Shaw, D. O. Clark, A. A. Davis, E. A. Devenish, J. K. Elliott, A. L. Eyre-Brook, L. Fatti, K. Fletcher Barrett, R. J. Furlong, J. Gabe, R. H. Hadley, C. S. Hallpike, J. Hardman, E. A. H. Hindhaugh, C. Hooper, Ruby D. Johnson, E. C. B. Jones, H. Y. Khwaja, C. E. Kindersley, S. Lal, M. Lee, M. J. F. McArdle, D. J. MacMyn, D. H. Mitchell, E. W. T. Morris, A. B. Pain, G. T. Partridge, R. S. Pilcher, A. E. Perritt, C. A. M. Renou, L. A. Riddell, T. O. Sayle, H. H. Skooch, J. O. Smith, S. B. Smith, F. R. Stansfield, S. C. Suggit, B. M. Sundaravadanan, G. L. Talwar, K. H. Watkins, F. E. Webster, Eileen M. Whapham, H. L. C. Wood.

Medical News.

THE Cavendish Lecture before the West London Medico-Chirurgical Society will be given to-day (Friday, June 21st), at 8.15 p.m., by Professor Claude Régaud, director of the Radio-physiological Laboratory of the Radium Institute, Paris, whose subject is "Progress and limitation in the cure of malignant diseases by radium." The meeting will be held in the Kensington Town Hall at 7.30 p.m., and at 8 o'clock the West London triennial gold medal will be presented to Sir Ronald Ross. The annual conversazione will follow Professor Régaud's lecture.

THE executive committee of the National Campaign Against Rheumatic Diseases, of which Sir Thomas Horder is chairman and Sir William Willcox vice-chairman, has called a meeting of supporters, to be held at the house of the Royal Society of Medicine, 1, Wimpole Street, W., on Wednesday next, June 26th, at 5 p.m. The agenda includes election of a council and the reception of a report by the executive committee on the policy and constitution of the campaign. All members of the medical profession interested in the subject are cordially invited to attend this meeting.

THE Section of Urology of the Royal Society of Medicine will hold its last meeting this session on Thursday, June 27th. From 11 a.m. to 1 p.m. there will be an exhibition of urological instruments, from 2 p.m. operations at St. Peter's Hospital, Henrietta Street, W.C.2, and at 8.30 p.m. a cinematographic demonstration showing a prostatectomy, litholapaxy, and internal urethrotomy. The demonstration will be made by means of a talking film, the operation as it proceeds being explained audibly.

THE annual provincial meeting of the Society of Medical Officers of Health will be held at the Sedbury Park Hotel, near Chepstow, on Saturday, June 29th, at 10.30 a.m., when Dr. E. Colston Williams (C.M.O. Glamorgan) and Dr. R. M. F. Picken (M.O.H. Cardiff) will open a discussion on the medical aspects of the Local Government Act, 1929. Luncheon will be served at 12.30 (tickets 3s. 6d. each). At 1.30 p.m. members will motor to Chepstow Castle, Tintern Abbey, and Raglan Castle, and thence to a garden party at Llanover Park, by invitation of Lord Treowen, Lord-Lieutenant of Monmouthshire, and Lady Treowen. The full programme has been circulated to members of the society with the current issue of *Public Health*.

THE Tuberculosis Association will hold its provincial meeting during the latter part of next week, in the Pharmacology Lecture Theatre, Medical School, Downing Street, Cambridge. At the opening session, on the afternoon of Thursday, June 27th, Dr. Franz Nagelschmidt of Berlin will read a paper on the prevention and healing of tuberculosis by turtle-vaccine therapy. On June 28th discussions, each opened by three speakers, will take place in the morning on the diagnosis of intrathoracic tuberculosis in children, and in the afternoon on the correlation of *x*-ray findings in pulmonary tuberculosis with the symptoms and physical signs. On the morning of June 29th there will be a discussion on gas poisoning and gunshot wounds of the chest in relation to tuberculosis.

THE sixty-sixth annual meeting of the British Pharmaceutical Conference will be held in Dublin next week from June 24th to 27th, under the chairmanship of Mr. R. R. Bennett, B.Sc., whose inaugural address, entitled "The changing foundations of materia medica," will be given on June 25th.

THE annual general meeting of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Tuesday, July 2nd, at 4.30 p.m. when the officers and council for 1929–30 will be elected and the report of the council, including reports by the treasurers, librarians, and editors, will be presented.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that the last two lectures of the M.R.C.P. evening course will be given at 11, Chandos Street, Cavendish Square, on June 25th and 28th, at 8.30 p.m.; the fee is 10s. 6d. per lecture, payable at the lecture hall. A free demonstration on nervous disease in children will be given by Dr. W. G. Wyllie, at 2.30 p.m., on June 27th, at the Hospital for Epilepsy and Paralysis, Maida Vale. A free clinical demonstration will be given by Mr. Harold Kisch, at 2 p.m., on June 27th, at the Central London Throat, Nose, and Ear Hospital, Gray's Inn Road. The following courses begin on Monday, June 24th: in proctology for one week at the St. Mark's Hospital, occupying all day, fee £3 3s.; in diseases of children for two weeks at the Children's Clinic and other hospitals, occupying most afternoons and some mornings, fee £2 2s.; and in medicine, surgery, and the special departments at the Prince of Wales's Hospital, Tottenham, occupying from 10.30 a.m. to 5.30 p.m., for two weeks, fee £5 5s., or £3 3s. for either week. In connexion with "Baby Week," the Fellowship of Medicine, at the request of the Maternity and Child Welfare Group of the Medical Officers of Health Society, has arranged lecture-demonstrations in London during the week July 1st to 6th. Various demonstrations, occupying the time from 10 a.m. until 4 p.m., will be given at the Queen Charlotte's Hospital on July 1st, followed by a lecture in the evening. On July 5th morning demonstrations have been arranged at the Tavistock Clinic for Functional Nervous Disorders, Tavistock Square, followed in the afternoon by a special demonstration at the Infants Hospital, Vincent Square. On July 6th there is a choice between two demonstrations, both taking place at 10 a.m., at the London Lock Hospital, Harrow Road, and at St. Thomas's Hospital. The fee for the whole course is 10s. 6d., and should be sent to the Fellowship of Medicine, 1, Wimpole Street, W.1, from whom syllabuses of this and all other post-graduate courses may be obtained.

TO mark the occasion of their forthcoming visit to the Annual Meeting of the British Medical Association in Manchester, Drs. Charles Horace Mayo and William James Mayo were elected honorary members of the Manchester Medical Society at the annual meeting, which was held on May 1st.

THE Academic Council of Queen's University, Belfast, on the recommendation of the Anatomical Association of Great Britain and Ireland, has awarded the triennial Symington prize in anatomy to Dr. H. A. Harris, assistant professor of anatomy, University College, and assistant to the Medical Unit, University College Hospital, in recognition of valuable contributions to anatomy, and especially of the paper on "The relation of skeletal ossification in the hind limb to the index of cerebral value of Anthony and Coupin."

THE Neech prize, offered annually for the best paper read before a Branch or Group of the Society of Medical Officers of Health, has been awarded for the session 1927–28 to Dr. H. Stanley Banks, medical superintendent of the City Isolation Hospital, Leicester. Dr. Banks's subject was the intensive serum treatment of severe diphtheria, and the

paper was read before the Fever Hospital Medical Service Group of the Society.

DR. OLIVER C. M. DAVIS was called to the Bar on June 12th by the Middle Temple.

THE proceeds of the Old English Garden Fête, which was held at the Royal Botanic Gardens on June 13th to 15th, have this year been donated to the Thank-offering Fund. Also to be devoted to the Fund are the profits from the sale of the reproduction of His Majesty's Message to his People, prepared by Messrs. Raphael Tuck, and now generally obtainable.

A VALUABLE article by Miss S. F. Cox and Dr. F. G. Spear on the radiological work of the Strangeways Research Laboratory, Cambridge, embodying accounts both of past work and investigations now in progress, is published in the May issue of the *British Journal of Radiology*.

SCHOLARS, medalists, and prizemen of University College, London, will be received on Thursday, July 4th, at 3 p.m., by Sir Walter Morley Fletcher, secretary of the Medical Research Council, who will afterwards address the Assembly. The new anatomy and physiology building (the gift of the Rockefeller Foundation), together with the museums and laboratories, and Sir Flinders Petrie's exhibition of recent discoveries of the British School of Archaeology in Egypt, will be open to inspection from 4.30 to 7 p.m.

A LARGE attendance of delegates from local authorities and voluntary child welfare institutions throughout the British Isles, and of Government representatives from the overseas Dominions, is expected at the fifth English-speaking conference on maternity and child welfare, to be held at the Friends House, Euston Road, N.W.1, from July 2nd to 4th. The maternity and child welfare group of the Society of Medical Officers of Health, in co-operation with the Fellowship of Medicine, has organized, in connexion with the conference, a short post-graduate course, of which full particulars will be forwarded to medical practitioners on application to the honorary secretary, National Association for the Prevention of Infant Mortality, Carnegie House, 117, Piccadilly, W.1.

THE third venereological congress of the Union of Soviet Republics will be held at Leningrad from July 1st to 7th, when the following subjects will be discussed: incidence and control of venereal disease in urban and rural districts, syphilis and constitution, congenital syphilis, dermatomycosis, complications of arsenical treatment, and control of gonorrhoea.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DIATHERMY OF THE TONSILS.

DR. M. Y. PAGET (Ware, Herts) writes for details of the removal of the tonsils by diathermy (a method which he understands is used in America and France), and for information about the advantages this method may have over that of surgical operation.

UMBILICAL DISCHARGE.

MR. A. P. BERTWISTLE, F.R.C.S.Ed. (London, W.), writes: In reply to "W. D.'s" query (June 15th, p. 1104) I would suggest that, the point of exit of the discharge having been identified, lipiodol be injected into the sinus. If, on radiographing, the fluid is found passing downwards towards or even into the bladder the condition is probably due to a urachal vestige. There is a remote possibility of it being allantoic in origin, however. The only method of treatment is complete excision of the track. If a trace is left in any of these congenital sinuses —for example, cervical or thyroglossal—the whole recurs.

LETTERS, NOTES, ETC.

ABOLITION OF FRENCH VACCINATION REGULATIONS.

THE Director of the Office Français du Tourisme, 56, Haymarket, S.W.1, writes: Some time ago you published information concerning the vaccination regulations which were in force in France; these were, however, cancelled on June 4th. In view of the numerous inquiries which still reach us on this matter, I should be much obliged if you would kindly inform your readers that no vaccination certificates or "passeports sanitaires" are now required when landing in France from the British Isles.

VACATION EMPLOYMENT FOR UNDERGRADUATES.

MR. RALPH NUNN MAY, B.Sc., Secretary of the National Union of Students (3, Endsleigh Street, W.C.1), writes: The enormous extension of facilities for university education in England has produced a phenomenon strange to us but familiar enough in the United States and Canada, and not unknown even in Scotland. In America it is common for men and women undergraduates to spend their vacations in some form of paid occupation enabling them to earn their keep during the summer months. In England this has been practically unknown, except for the few senior scholars who have coached the sons of the well-to-do for school or university examinations. There is a limit to the number of wealthy parents anxious for the mental attainments of their children, and the opportunities for private coaching, never very great, are now quite inadequate to absorb the number of undergraduates from the old and the modern universities, who come very often from lower-middle or working-class homes, and who are anxious both to gain experience and to earn a living wage during July, August, and September. Applications are now reaching us from undergraduates all over the country who wish to find such temporary employment. But in a country where this is not traditional, where are we to find the firms or persons who will offer them posts or consider their employment during a seasonal rush period? Generally they are willing to do almost any kind of work—as labourers, shop assistants, waiters or waitresses, governesses, and so on. Some of the senior science students might be capable of acting as works chemists or physicists to replace staff on holiday. There is obviously a great number of ways in which they might usefully be employed to their own advantage, and possibly also to the ultimate advantage of industry. We have every desire to avoid the displacement in any way of normal or regular labour, but if there are any employers who, while bearing in mind this cardinal point, might still be able to offer temporary employment to university men or women we should be deeply grateful to hear of them.

HERPES AND VARICELLA.

DR. R. C. WORSLEY (Topsham, Devon) writes: I have often smiled, with others, at the appearance of the above perennial large gooseberry, but two striking cases in the last week have convinced me that there is "something in it." An old man had very bad shingles on his arm, shoulder, and back; a fortnight after its appearance his wife, some years younger, had the worst attack of chicken-pox I ever have seen in nearly forty years. (The patient was so ill that four doctors met to establish the differentiation from small-pox.) Three miles away, in a small village, a man had a severe attack of shingles on the leg, buttock, and scrotum, which ulcerated in parts. Two weeks after the onset his daughter developed varicella. There are, to my knowledge, no other cases of the latter disease in our neighbourhood.

NORTH-EAST COAST EXHIBITION.

THE Committee of the Medical Institute (J. Wilkie Smith Memorial), 7, Windsor Terrace, Newcastle-upon-Tyne, ask us to announce that the facilities of this institute are open to any medical man visiting the North-East Coast Exhibition at Newcastle. Bed and breakfast, 10s. 6d.

INDEXES TO "JOURNAL" WANTED.

DR. E. F. ARMOUR (6, Bruntsfield Terrace, Edinburgh) requires the following out-of-print Indexes to the *British Medical Journal*, and would be grateful to any reader who could supply him with all or any of them: General, Supplement, and Epitome Indexes, 1916, vol. i, and 1918, vol. ii; Epitome Index only, 1915, vol. i, 1916, vol. ii, 1918, vol. i, and 1919, vol. i. Cost of postage would be repaid.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 247.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

590. Dyspnoea and Polypnoea of Cardiac Origin.

L. GALLAVARDIN (*Lyon Méd.*, March 17th, 1929, p. 313) remarks that the term "dyspnoea" is commonly used to denote two quite distinct conditions, both the result of some degree of effort. He would prefer to use the terms "polypnoea" and "dyspnoea," in their strict etymological sense, for these two conditions. He considers that the first is essentially comparable with the increased respiratory exchange occurring as the physiological response to effort; although it may occur in a very wide variety of types of cardiac insufficiency, it has certain constant features: (1) It is directly proportional to the amount of effort producing it. (2) The usual sequel in extreme cases is the production of ventricular dilatation with pulmonary oedema. (3) It is never accompanied by the true anginal syndrome; sometimes there may be a feeling of tension in the epigastric region, even amounting to actual pain, but there is never the typical radiating pain of angina, and he suggests the use of the term "para-dyspnoeic angina" to describe it. (4) The patient experiences a feeling of breathlessness and not of suffocation. (5) Atmospheric conditions do not influence the condition except when they add to the effort, as, for example, progress against the wind. The second condition of "dyspnoea" is described as the counterpart of the physiological difficulty in breathing experienced in facing a strong wind, when there appears to be an actual difficulty in filling the lungs with air. As in the first instance, a large variety of pathological conditions of the heart may be found, but the constant features are as follows. The severity of the symptoms is not proportional to the amount of effort, which may, indeed, be trivial; the typical sequel is the appearance of the true anginal syndrome; there is no feeling of breathlessness, but rather of suffocation, and an impression that persistence in the causative effort will end in collapse; atmospheric conditions have a marked effect on the dyspnoea, and some patients are quite unable to go out in windy weather, particularly with cold or snow, without the certainty of having an attack. Gallavardin considers that the dyspnoeic syndrome has its origin in spasmodic phenomena which lead to reflex inhibition of the respiratory act. He notes that the two conditions described may quite commonly alternate in the same subject, according to the provocation. In conclusion he emphasizes the importance of distinguishing between the "compensatory polypnoea," which is the common reaction in cardiopathy with poor compensation, and the more rare "dyspnoea by inhibition," which may be regarded as a minor manifestation of true angina pectoris.

591. Diabetes and Exophthalmic Goitre.

M. LABBÉ and G. DREYFUS (*Paris Méd.*, May 4th, 1929, p. 429) think that the association of Basedow's disease with diabetes, though not very common, is too frequent to be a mere coincidence; that there is a morbid relation between the two diseases; and that the constant disturbance of glyco-regulation revealed by hyperglycaemia in the latter proves that thyroid hyperactivity exerts an influence on sugar metabolism. Usually the goitre appears first in this association, though sometimes this order is reversed. According to Joslin and Lahey and Wilder, toxic adenomatous or secondary goitre is the most often accompanied by diabetes; the primary type is less responsible. The pathological picture is that of an intense exophthalmic goitre, in which the basal metabolism reaches a higher level than in the simple forms. The diabetes is of varying gravity, ranging from a benign thyroid glycosuria to a grave diabetes with nitrogenous denutrition and acidosis. Death is usually due to coma, which, as a rule, is an ordinary acidosic coma, though cardiac collapse may be associated with the acidosis. In the majority of cases the two conditions evolve together and undergo simultaneous recrudescences. This has caused Labbé to suggest that the pathogeny of thyroid diabetes is distinct from that of the pancreatic type. In the former the glyco-regulating disturbance is due to the hyperthyroidism, and in the latter to insufficiency of the insulinic secretion. Many organs have an influence on glyco-regulation; among these the pancreas and the thyroid have antagonistic actions. The former lowers glycaemia and fixes the glycogen in the liver; the latter raises the glycaemia, removes glycogen from the liver, and activates its transformation into glucose. Thus pancreatic insufficiency has the same result as hyperthyroidism—it abolishes the glycogenic function and causes diabetes. The results of numerous animal experiments and observations in goitre cases bearing on this point are cited. The authors quote the experiences of several authorities in treatment; these all show that the active treatments of the goitre by iodine, *x* rays, and thyroidectomy exercise simultaneously a favourable effect on the diabetes, which is less influenced by diet and insulin than the pancreatic form. The exact pathogeny of diabetes associated with goitre is complex, and the glyco-regulating trouble results not only from insufficiency of insulin but also from excessive secretion of thyroxin. Two cases are reported.

592. The Blood Pressure in Influenza.

C. GOTTHEIL (*Deut. med. Woch.*, April 19th, 1929, p. 648) has studied the blood pressure changes associated with the circulatory disturbances frequently observed in influenza in a number of cases in which there was no evidence of valvular or muscular damage to the heart, and in which the symptoms could therefore be ascribed to central or peripheral damage to the vessels. In nearly every instance the systolic pressure was slightly raised as compared with the value obtained during convalescence, and the diastolic was considerably diminished, down to 30 mm. of mercury or less, giving a very large pulse amplitude such as generally only occurs in aortic incompetence. In a few cases capillary pulsation was also observed. This low diastolic pressure, which occurred in 40 of the 50 patients examined, seemed to be independent of the severity, duration, or localization of the influenzal attack, and of the age of the patient. In contrast to previous epidemics, the pulse rate was generally raised in proportion to the temperature. In certain other acute conditions, such as lobar pneumonia, which at the onset resembled influenza, this low diastolic pressure did not occur, and this fact was found of value in early differential diagnosis. As the infection subsides the diastolic pressure gradually returns to normal; this may either precede defervescence or follow many days after the temperature has subsided. It is suggested that the cause of the fall in diastolic pressure is primary damage and paralysis of the capillary system.

Surgery.

593. Foreign Bodies in Joints.

P. MOULONGUET (*Journ. Bone and Joint Surg.*, April, 1929, p. 353) divides foreign bodies in joints into two groups—those of synovial and those of osseous origin. Those of synovial origin occur in arthritis deformans and nerve arthropathies, and also in apparently healthy joints where the arthritis is very localized. Osteocartilaginous foreign bodies are the most important lesions in this group, and are usually of pathological origin, formed from the synovial membrane or from the bone terminals. Trauma appears at times to be the origin of these foreign bodies and of a dry arthritis; occasionally it breaks the pedicle of the foreign body already formed and functional disturbances follow. Arthrotomy, with the removal of all foreign bodies, is the operation of choice, excision being harder in the hip than in other joints. The dry arthritis, after a complete cleaning out of the articulation, may recede. The various types of foreign bodies of osseous origin are: the osteophytes, detached from the epiphysis; those developed about the fragments of necrosis of the articular surfaces; and those foreign bodies of osteochondritis dissecans. The foreign cartilaginous body develops round a small exfoliated osseous sequestrum. Osteochondritis dissecans may be indicated by pain at a fixed point at the edge of the joint or by a blocking of the joint. Treatment must be surgical, the sequestrum being removed from its lodgment, and the cartilage being cut round to raise the fragments from underneath toward the outside. Traumatic foreign bodies are very rare, but can be differentiated from those of the osteochondritis, which are free in the articulation, by being covered and given a pedicle by the synovia. In cases of traumatic foreign bodies there should be complete cure after operation, but when there is a pathological origin the condition is liable to recur, especially in the course of a severe irremediable articular lesion, including nerve arthropathies and general arthritis deformans, and in cases where there is an exuberant formation of foreign bodies in the serous bursae and the synovia as well as in the articulations. Surgical prognosis is good when foreign bodies of synovial origin exist without another important lesion in the articulation, and in foreign bodies of bony origin, especially those in osteochondritis dissecans.

591. Gas Gangrene in Peace Time.

M. SIEBNER (*Deut. Zeit. f. Chir.*, April, 1929, p. 59) states that though gas gangrene due to the Welch-Fränkel bacillus has been much rarer since 1918 than it was during the war, six cases have occurred among 4,500 patients in the surgical department of the Marien Hospital at Stuttgart in the course of the last three years. In each case the infection was connected with damage to the extremities (in one the upper and in five the lower) by vehicles or machines, the wounds being grossly contaminated by earth or dust. The ages of the patients ranged from 6 to 47 years. In three cases the wounds were complicated by compound fracture. In two cases recovery followed amputation, while the remaining four ended fatally. Serum treatment probably contributed to the recovery of one patient, so that, in addition to antitetanic serum, 10 to 20 c.cm. of polyvalent gas gangrene serum should be employed prophylactically in all wounds in which there has been a possibility of infection with anaerobic bacilli. In such cases excision of all damaged tissues and opening up of all pockets are important. Everything should be avoided which is liable to diminish free circulation through the tissues, such as adrenaline, tight dressings, and pressure by splints. As pain in the wound is an early symptom of gas gangrene, the occurrence of this symptom should demand immediate examination of the wound. Absence of an inflammatory reaction round the wound is characteristic of gas gangrene, as is also a rapid pulse with a low temperature. On the first suspicion of gas gangrene the wound should be freely opened and the infected parts removed as far as possible. If the infection is not too acute, Bier's treatment should be adopted. Amputation is usually inevitable when several groups of muscles are attacked and the infection has invaded the neighbouring joint. Maintenance of the heart's action by adrenaline, caffeine, or the intravenous injections of glucose is necessary, as death is usually due to cardiac paralysis.

595. Fatal Air Embolism.

AIR embolus has long been recognized as the cause of alarming symptoms or death following the inflation of the bladder or urethra with air for diagnostic and operative procedures, and its occurrence is said to be rather common. C. P. MATHÉ (*Surg., Gynecol. and Obstet.*, March, 1929, p. 429) emphasizes the danger of this measure, and reports a case of sudden death following such inflation. He maintains that the distension of the bladder or urethra with air or oxygen for any purpose may result in transitory or grave symptoms should it enter the venous circulation; he asserts that its use should be abandoned, and harmless sterile water or mild antiseptic solutions be substituted. Increased intravesical or intraurethral pressure is favoured by prostatic hypertrophy or by stricture formation, which prevents the escape of air between the urethral walls and the indwelling catheter or cystoscope. Rupture of the vesical mucosa by over-distension, or the presence of a pre-existing inflammation, ulcer formation, or a new growth, weakens the bladder wall, thus favouring the entrance of air into the venous circulation. Mild symptoms, consisting of restlessness and transient changes in the respiratory and cardiac action, have undoubtedly been overlooked, as has also the cause of fatal termination. Death is due to the arrest of the pulmonary circulation; to gaseous distension of the right heart interfering with the function of the tricuspid and pulmonary valves; to little blood reaching the left ventricle, so that anaemia of the vital centres of the brain is produced; and to stasis of the coronary vessels. The most effective treatment of air embolus is the immediate release of air pressure in the bladder, artificial respiration, and injection of 2 c.cm. of a 1 in 1,000 adrenaline solution directly into the right side of the heart.

596. Haemolytic Jaundice Treated by Splenectomy.

F. WIDAL, L. DE GENNES, and LAUDAT (*Presse Méd.*, April 20th, p. 513), although regarding congenital haemolytic jaundice more as a defect than a disease, describe a case in which splenectomy was performed by them owing to the persistent demand by their patient for operation. The result was markedly successful, and the general health of the patient was greatly improved, as were the more specific physio-pathological conditions. The jaundice, which had persisted for twenty-three years, completely disappeared, except when the patient became unduly fatigued or run down in health. The red cell count gradually rose from 2.5 million per c.mm. to 4.9 at the end of two years. Detailed tables are given showing the changes and improvements in the blood as regards corpuscular fragility, haemoglobin, cholesterin, and lipoids. The authors emphasize the dissociation between the evolution of the anaemia and that of the corpuscular fragility, and comment on the apparent parallelism of the curves of the resistance of the corpuscles and the lipoidal content of the serum.

Therapeutics.

597. The Sulphur Iodide Treatment of Cataract.

E. GINESTOUS (*Gaz. Hebd. des Sci. Méd. de Bordeaux*, March 10th, 1929, p. 152) considers that undoubted success has followed medical treatment of cataracts, and cites Badal's opinion of the efficacy of iodides in these conditions. The latter's formula has remained the basis of subsequent medical treatments of cataracts, though it has been modified by various authorities, Dor, for example, adding calcium chloride as a dehydrating agent. The organic tissues contain an albuminoid body, philothion, which with sulphur gives sulphuretted hydrogen. The tissues of the crystalline lens are rich in this substance; therefore De Rey-Pailhade concluded that sulphur would have an action on this organ, and Molinery that the philothion of the lens by its affinity for oxygen would become catalytic, and that this catalysis would increase in the presence of sulphur at the expense of the bodies causing the opacity of the lens by lysing either the sclerosed connective tissue or the calcareous products, factors of the cataract. For two years Ginestous has treated cataracts with sulphur in combination with iodides and calcium, and employs a mixture, compounded by Bazin, of the following formula: precipitated sulphur, 10 cg.; oil of sweet almonds, 2 grams; crystallized calcium chloride and dried sodium iodide, aa. 40 cg.; neutral vaseline and lanoline, aa. 5 grams. A piece the size of a pea is put into the eye morning and night. These applications are generally painless and cause no inflammatory reaction. In very rare cases a burning sensation is experienced, which can be prevented by adding 10 cg. of stovaine or, preferably, of butelline. Internal treatment, governed by the general state of the patient and the etiology of the cataract, should be given simultaneously. This treatment is useless in congenital or old cataracts or in those due to traumatism. It is beneficial in diabetic cataract, and especially so in senile forms. Genestous reports that, in more than 50 cases treated by this method at their commencement, the opacity not only did not progress but showed actual regression.

598. Calcium Treatment of Pulmonary Tuberculosis.

F. BECKER (*Zeit. f. Tuberk.*, April, 1929, p. 198) records his observations in 78 cases of pulmonary tuberculosis treated by intravenous injections of calcium chloride during the course of the last two and a half years. Of these patients, 28 were in the second and 50 in the third stage of the disease, according to the Turban-Gerhardt classification. In 61 instances the tuberculosis was "open" and in 17 "closed"; 67 were cirrhotic forms, 10 were mixed, and one was a case of purely inflammatory exudation. Cases with early infiltration were not subjected to the treatment. Of the 78 cases, there was distinct improvement in 59, 16 showed no change in the symptoms or physical signs, and 3 could not tolerate the treatment. Of the 61 "open" cases, only 7 became "closed" during the treatment—a small but remarkable proportion in view of the fact that the disease was usually extensive and of long standing. Becker comes to the conclusion that the method is of value in the treatment of pulmonary tuberculosis, especially in cases of bilateral disease.

599. Silver Preparations in Conjunctivitis.

BIRNBAUM (*Le Scalpel*, April 6th, 1929, p. 369) advocates the use in conjunctivitis of a new preparation of silver which, he claims, has already proved beneficial in various diseases such as enteritis. The two methods commonly used in conjunctivitis—namely, the instillation of preparations of silver compounds in the acute stages and of the astringent, zinc sulphate, in the chronic stages — have certain disadvantages. Silver nitrate precipitates the albumin and causes a subsequent irritation with hypersecretion. It forms an eschar and only the superficial micro-organisms are destroyed, while the subjacent tissues are irritated and, becoming hyperaemic, form a suitable nidus for bacterial development. Colloid silver has a greater penetrative power, but it is only a weak bactericide. Strong solutions of zinc sulphate are caustic, while weak ones are useless, and, in general, the efficacy of zinc is limited to a very short period. Birnbaum's preparation combines diacetyl tannin and silver albuminate. He states that it is not an irritant, despite the large amount (6 per cent.) of silver it contains, and that it does not cause excessive secretion. It is said to have a remarkable astringent action, much greater than that of zinc, and not to be caustic. Experiments have shown that it has considerable penetrating power as well as bactericidal action, though the latter is only half that of protargol. The preparation may be used in both acute and chronic conjunctivitis.

Dermatology.

600. Seasonal Bullous Dermatitis.

H. W. SIEMENS (*Münch. med. Woch.*, March 15th, 1929, p. 449) describes in detail four cases of dermatitis occurring in persons who had lain on the grass after bathing in rivers or bathing pools, and four other cases reported a year ago and re-examined. The lesions appeared within twenty-four to thirty hours on some only of the areas of skin which had come into direct contact with the grass; they were linear in form and were associated with irritation and a burning sensation. The centre subsequently became bullous, and when the bullae dried up about the sixth day pigmented spots remained which persisted for several months. All the patients had bathed in different places and none had previously suffered from similar attacks, though all were apparently in the habit of lying on the grass after bathing—one in exactly the same part of the same meadow. The plants growing in those parts of the meadows used by the bathers were examined and identified by Professor von Goebel, and attempts were made to reproduce the lesions by rubbing suspected plants into the skin and by strapping them on to the skin for twenty-four hours; the results were all negative. As Oppenheim and Peszler had suggested that the dermatitis might be due to hypersensitiveness of the patients to silicic acid, of which some grasses contain a high percentage, the sensitiveness of the patients to applications of sodium silicate and to very fine quartz sand was also tried, but no reaction resulted. Finally, in order to ascertain whether the skins of these patients were particularly sensitive to mechanical stimuli, finely powdered glass wool was applied. No reaction resulted from this nor from the application of barley dust, which contains very fine sharp spicules. The pathogenesis of the condition thus remains obscure, and Siemens concludes that though clinically the cases of this bullous linear dermatitis resemble one another closely, they are not due to one particular plant, but that an unknown factor, possibly the preliminary soaking of the skin (during bathing), sweating, or insolation, plays an important part in the etiology of the "conditioned hypersensitiveness" to which this form of dermatitis appears to be due.

601. DURING the last two years, V. GENNER (*Ann. de Derm. et de Syph.*, March, 1929, p. 269) has noted in Copenhagen the appearance during the late autumn of a dermatitis of a type which he thinks has not yet been recorded, and reports ten cases of the disease—nine in women and one affecting a boy aged 15. The affection was characterized by a very small number of disseminated, rounded bullae, some of which were about one inch in diameter. The contents, at first serous, quickly became purulent. The bullae were surrounded by a slight erythematous zone, but there was no infiltration; they reached their full development in twenty-four hours. Itching was absent or only slight. Primary lesions, such as papules, were never found. The affection was exclusively confined to the lower half of the legs, especially behind and above the malleoli. Treatment consisted in opening and evacuating the bullae, and applying a dressing of vaseline or silver nitrate ointment; this produced a rapid cure. Genner alludes to a similar seasonal affection occurring in Germany, and also to one in Japan, and remarks that bullous dermatitis may be caused by stings from plants or insects. In the former the eruption is almost always accompanied by characteristic erythematous changes and intense itching. From the absence of these features, the fact that the patients when infected were always in the open air, and the localization of the lesions to the lower limbs, Genner concludes that the present cases were most likely due to the bite of an insect.

602. The Etiology of Chronic Febrile Pemphigus.

THE obscure etiology of pemphigus has prompted J. SABRAZÈS and J. TORLAIS (*Gaz. Hebd. des Sci. Med. de Bordeaux*, April 7th, 1929, p. 209) to describe a case in a woman, aged 47, who came under their care for several months previous to her death. The bullae began in the buccal cavity and on the soft palate, assuming a haemorrhagic character at times. Later the back and chest were affected. There was no relevant previous history, but the patient had old-standing pyorrhoea alveolaris with greenish pus, and obstinate constipation with extremely fetid stools. From a blood culture *B. mesentericus vulgatus* was recovered; there was pyuria, and a pure growth of *B. coli* was obtained from the urine. The lungs, heart, and other viscera appeared normal. Treatment with mercurial ointment made the pyorrhoea worse without helping the pemphigus. There was considerable oliguria, only 500 to 600 c.cm. of urine being passed daily; at times the temperature rose to between 103° and 104° F. Later a large retro-trochanteric boil developed, which became an ulcer 4 inches in diameter, reaching down to the capsule of the hip-joint. Treatment consisted of antiseptic dressings and lavage with Dakin's solution and light vitaminiferous diet. The condition of the patient, however, steadily became worse, and in spite of diuretic treatment only 200 c.cm. of urine were passed in the twenty-four hours. Bullae continued to develop in the sternal, dorsal, and lumbar regions, and on the thighs, the total surface being vast. Details are given of the various pathological examinations of the blood and of the serous material from the bullae. The protein content of the blood serum was found to be little more than half the physiological amount, and the authors discuss the permeability of the cutaneous capillaries in the light of their findings of the protein and chlorides with regard to local oedema and bulla formation. Unfortunately no post-mortem examination was permitted.

603. Treatment of Annular Granuloma.

A. SÉZARY and A. DURCY (*Bull. de Derm. et Syph.*, March, 1929, p. 270) describe the results of treating with Vaudremer's vaccine two cases of annular granuloma which gave clearly positive skin reactions with tuberculin. The vaccine used in both cases was described by Sézary and Vaudremer in the same journal in February, 1927, and consists of a suspension of the non-acidophile granules of Koch's bacilli. It was injected twice weekly, and one or more courses of twelve doses were given. The adult dose began with 0.25 c.cm., and was increased gradually to 1.75 or 2.0 c.cm.; in a child the maximum dose was 0.5 c.cm. No general reaction was observed. In the first patient, a child aged 10, typical annular granuloma appeared in 1925 on the left index finger, and later other fingers and one ear became affected. Under ultra-violet treatment the first lesion disappeared, but the others remained obstinate. After the fifth injection of Vaudremer's vaccine they became modified in appearance, and after a second course all completely disappeared except the oldest lesion. The second patient, a woman aged 38, was first attacked on the back of the left hand, and, later, on the dorsal surfaces of the index and second fingers. Here again the last lesion to develop completely vanished under treatment; the original one was greatly modified, and the authors think that in time it may also be cured.

Obstetrics and Gynaecology.

604. Glycosuria and Acetonuria as Signs of Pregnancy.

O. PORGES and D. ADLERSBERG (*Wien. Arch. f. innere Med.*, April 10th, 1929, p. 1) call attention to the occurrence of spontaneous glycosuria during pregnancy, and the importance of this symptom in the diagnosis of that condition. According to several Continental authorities, this glycosuria depends upon an increased permeability of the kidneys in regard to sugar—that is, a renal glycosuria is established. Two writers have suggested the probability that the alimentary glycosuria observed in pregnant women is also of renal origin. Frank found an increased desire for sugar in a higher percentage of pregnant women than among normal persons, although hyperglycaemia and glycosuria did not occur. Many gynaecologists and obstetricians have accepted these conclusions, but other authorities have recorded numerous errors in diagnosis. The present authors think, therefore, that the occurrence of renal glycosuria in a young woman is not a definite proof of pregnancy. On the other hand, it has been shown that during pregnancy a varying degree of acetonuria is usual, the onset of which indicates exhaustion of the patient's carbohydrate metabolism and carbohydrate reserve. It is to be expected that in pregnancy (as compared with the non-pregnant state) a dietary of low carbohydrate content would have a greater effect upon carbohydrate metabolism, as the pregnant woman stands in greater need of carbohydrates. Alimentary acetonuria has been proved, therefore, to be of greater importance in the diagnosis of pregnancy than is alimentary glycosuria. The authors observed 30 primiparae and 24 controls, who consisted of healthy adults of both sexes, with a proportion of patients suffering from various internal, non-febrile diseases. It was found that every pregnant woman, after one day's carbohydrate-free diet, exhibited a positive acetone reaction in the urine, and the amylase deficiency caused a definite, though slight, glycosuria. Among the twenty-four controls two cases of Graves's disease exhibited an alimentary acetonuria, and three other cases an alimentary glycosuria; in every instance this occurred after the patients had received a mixed diet. The authors conclude that the simultaneous occurrence of both glycosuria and acetonuria is a more valuable diagnostic test of pregnancy than any of the hitherto accepted biochemical reactions.

605. Valvular Hydrosalpinx.

ACCORDING to C. BÉCLÈRE (*Gynécol. et Obstét.*, March, 1929, p. 191), hydrosalpinx in which both abdominal and uterine ends of the tube are closed is considerably more rare than valvular hydrosalpinx, which is usually bilateral and in which only the abdominal ostium is closed. In valvular hydrosalpinx egress of the effusion into the uterus is impossible; but fluids injected into the uterus can pass as through a valve under pressure, and, gaining access to the tube, give rise to a highly characteristic radiographic picture when lipiodol has been used. The essential diagnostic sign after lipiodol has been injected is the retention within the tube of the opaque fluid; this retention is shown by a control examination which can conveniently be made twenty-four hours afterwards, but also still later. A second sign, not invariably detected, is the demonstration during screen examinations of entry of the fluid and its accumulation in the tube in the form of spherical drops regularly succeeding each other. These signs have been described by numerous French and other observers, working independently. From an anatomical point of view, there is a contrast between the naked-eye appearances, which show neither adhesions nor abscess, and the microscopical characters, which are those of definite but slight inflammation. Some folds, with their epithelium, are preserved, the mucosa shows polymorphonuclear infiltration, and in the muscularis there is inflammatory regression. Signs of tuberculosis are sometimes present. Clinically the patients may have had one or more pregnancies, but more usually they are sterile, and the inception of the hydrosalpinx dates from the first sexual congresses. Commonly, as a result of infection from the husband by a gonococcus of attenuated virulence from an old lesion, there result sterility, slight yellow discharge, and repeated slight abdominal pain. Bimanual examination, except occasionally in the case of very large hydrosalpinges, usually reveals no gross adnexal swelling, although the fornices may be boggy and tender. It is therefore by radiographic examination only that early valvular hydro-salpinx is likely to be detected. Treatment even at this stage is unfortunately not hopeful with regard to the sterility, and not more than 5 per cent. of successes are claimed for salpingostomy. Recourse must too often be had to subtotal hysterectomy, or, better, to excision of the fundus, which at least conserves the menstrual function.

606. Hyperplasia Endometria and Carcinoma Corporis Uteri.

C. F. FLUHMANN and H. A. STEPHENSON (*Surg., Gynecol. and Obstet.*, March, 1929, p. 425) state that the association of hyperplasia of the endometrium with malignancy of the body of the uterus is rare, and only a few cases have been reported. R. Meyer, who recorded five cases, showed that an adenomatous cancer may not only have its origin in hyperplastic mucosa, but may arise directly from previously simple hyperplastic glands. The present authors report a case of marked hyperplasia of the endometrium accompanied by an adenomyosis uteri; in the endometrium was found an early adeno carcinoma, which arose apparently from hyperplastic glands. A complete hysterectomy with removal of the tubes, ovaries, and cuff of the vagina was performed. No adhesions and no enlarged glands were found, and the patient made an uneventful recovery. Apparently, as was shown by the specimen, all the cancerous tissue was removed by the curette, a possibility reported by other observers. Though some authors believe that hyperplasia of the endometrium predisposes to cancer, the general consensus of opinion is opposed to this view. Fluhmann and Stephenson state that hyperplasia may be followed by cancer, and emphasize the importance of careful study of all tissue obtained from the uteri of women with abnormal bleeding at the time of the menopause.

Pathology.

607. Vaccination with Dead Tubercle Bacilli.

S. A. PETROFF, A. BRANCH, and F. B. JENNINGS (*Journ. Immunol.*, March, 1929, p. 233) find that it is possible to establish skin hypersensitiveness in guinea-pigs by the intratesticular or intraperitoneal injection of heat-killed tubercle bacilli. In order to determine whether guinea-pigs sensitized in this way were immune to tuberculosis they performed the following experiment. Seventy-five guinea-pigs were sensitized by the intraperitoneal route with dead tubercle bacilli, three doses being given within a week, an equal number being kept as controls. A fortnight after the last injection 95 per cent. of the vaccinated animals reacted positively to the intracutaneous tuberculin test, while all the controls were negative. Each batch of animals was then formed into three groups, which were injected subcutaneously with different doses of living virulent human tubercle bacilli; the experiment was terminated after 630 days. The results were as follows: Group A1 of vaccinated animals received a dose of 440 organisms; Group A2 of control animals received the same dose. The total mortality (from both tuberculosis and intercurrent disease) among the A1 group was 54 per cent., among the A2 group 96 per cent.; the average survival time of the A1 group was 369 days, of the A2 group 295 days. Group B1 of vaccinated and Group B2 of control animals received a dose of 4,400 organisms: B1 had a mortality of 75 per cent. and an average survival time of 273 days; B2 had a mortality of 96 per cent. and a survival time of 236 days. Group C1 of vaccinated and Group C2 of control animals received a dose of 44,000 organisms: C1 had a mortality of 90 per cent. and a survival time of 303 days; C2 had a mortality of 100 per cent. and a survival time of 168 days. The authors conclude that, provided a small infecting dose is used, it is possible to show that guinea-pigs vaccinated with dead tubercle bacilli have a substantial immunity to experimental tuberculosis. They consider that a vaccine of heat-killed tubercle bacilli might profitably be used for the vaccination of children.

608. Cardiac Metabolism.

M. HAENDEL and A. MUNILLA (*Anal. de la Fac. de Med.*, February, 1929, p. 183) examined the cardiac, muscular, and hepatic glycogen and glycaemia in dogs after intraperitoneal injection of 2 grams of glucose per kilogram of body weight and of various pharmacodynamic substances, with the following results. Glycogen values in control animals amounted to 0.561 per cent. in the heart, 0.243 per cent. in the muscles, and 1.2519 per cent. in the liver. In digitalized animals there was a considerable fall of cardiac glycogen, but the glycogen in the other organs did not undergo any considerable change. Toxic doses of ouabain caused a general mobilization of glycogen, while small doses lowered the cardiac glycogen and to a slight extent the hepatic glycogen, causing hyperglycaemia. Toxic doses of camphor caused general mobilization of glycogen, while smaller doses had no influence on cardiac glycogen; there was hyperglycaemia. The action of caffeine was like that of camphor, except that its action on muscular glycogen was more pronounced. Potassium chlorate had no action on cardiac glycogen, though it acted on other glycogens and gave rise to hyperglycaemia. Calcium chloride caused a remarkable diminution of cardiac glycogen, and in large doses produced a general diminution of glycogen with hyperglycaemia. Adrenaline also caused general diminution of glycogen. The authors found that in normal animals the cardiac glycogen was independent of the action of insulin, contrary to what occurs in depancreatized dogs. Thyroxin had very little effect on cardiac glycogen, whereas it mobilized muscular and hepatic glycogen.

609. Relapsing Fever Spirochaetes in the Brain of the Mouse.

C. LEVADITI and T. E. ANDERSON (*C. R. Soc. de Biologie*, April 26th, 1929, p. 1121) record some experiments on the infectivity of the brain of mice inoculated with *Treponema duttoni*. Several workers have now shown that the brain may be infective long after the spleen and other organs of the body have become avirulent. The authors in their first experiment grafted the brain of a mouse, killed 99 days after infection, beneath the skin of the abdomen of six normal mice. Examination of the grafts at varying intervals failed to reveal the presence of spirochaetes. Nevertheless, the spleen and the blood of the mice became infective about the third day, though microscopically spirochaetes were not demonstrated till after four to seven days. In a second series of experiments the virulent brain of a mouse, killed 52 to 112 days after inoculation, was injected intraperitoneally in a finely suspended state into normal mice. The results showed that the blood, and with less constancy the peritoneal fluid, became infective after about twelve hours, and the spleen after about forty-eight hours. No spirochaetes were found microscopically, however, till the fourth or fifth day. Filtration experiments made on the virulent brain or peritoneal fluid were unsuccessful. Even with filters of compressed glass having large pores the infecting agent failed to pass into the filtrate; not until filters with an estimated pore size of 25 to 36μ were used did the filtrate prove infective. From these experiments the authors conclude that the virus of relapsing fever persists for a long time in the brain of the mouse, in an invisible form, probably within the cells. When it is inoculated beneath the skin or into the peritoneum of normal mice it promptly invades the blood stream, and in the course of a few days becomes transformed into the typical spirochaetal form.

RHEUMATOID-ARTHRITIS
LUMBAGO SCIATICA
NEURITIS

ALL THESE CONDITIONS YIELD RAPIDLY TO A COURSE OF

ELIXIR FORMASAL CO. AND TAB. ARTHRITONE

The combined treatment is giving excellent results in cases of Rheumatoid Arthritis which have stubbornly resisted all other forms of medication.
The results that are being obtained by the profession are very striking and no practitioner can afford to be without a supply.

Please note, our preparations are not advertised to the public.

Price

ELIXIR FORMASAL CO. 4/3 lb, WINCHESTER 4/- lb.
TAB. ARTHRITONE 4/6 Per 100 — 32/6 Per 1,000.

HOUGH - HOSEASON & Co. Ltd MANCHESTER
PHARMACEUTICAL SPECIALISTS TO THE MEDICAL PROFESSION.

Valentine's Meat-Juice

In **Vomiting** of **Pregnancy**, in the **Exhaustion** following **Hemorrhage** or **Prolonged Labor**, and before and after **Abdominal Operations** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been **Demonstrated** in

Hospitals for Women.

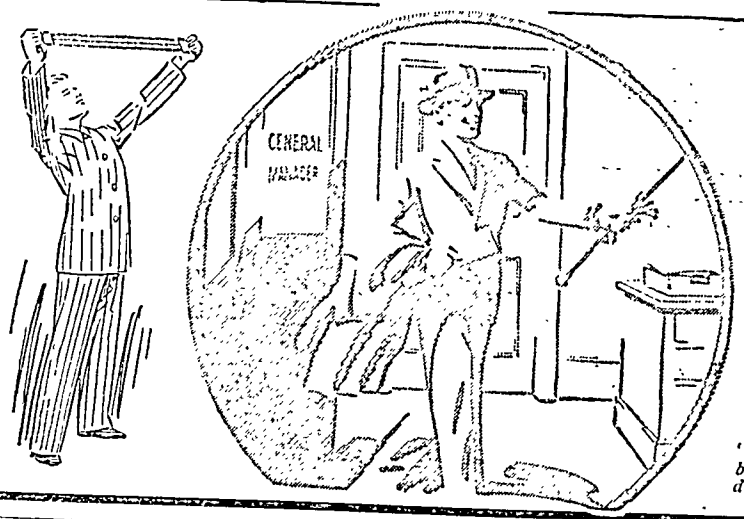
The quickness and power with which **Valentine's Meat-Juice** acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for Clinical Reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

JB 96



There's a reason why the busy man wears

"Tricoline"

SHIRTS, COLLARS & PYJAMAS

A Wemco Fabric.

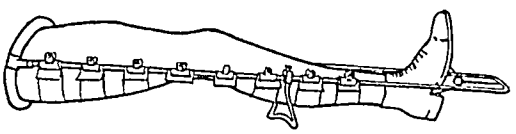
IT is because, in addition to their comfort and economy, they represent the finest value and variety that can possibly be offered. Thoroughly well made in a wide choice of plain shades and tasteful stripes, all the colours are guaranteed fast to laundering.

"TRICOLINE" SHIRTS, COLLARS and PYJAMAS are sold by leading Hosiers, Outfitters, and Stores everywhere. If any difficulty, write M 15, "TRICOLINE" House, 19, Watling Street, London, E.C.4.

COLLENDER'S SPLINTS

(Patented in many Countries)

Combine the advantages of the Thomas Splint with many improvements and additions.



They are supplied in fitted cases. The larger set provides material for treating ten fractures simultaneously.

Advantages:

They ensure accurate extension and safe transport. They are adjustable to any length of limb. All parts are interchangeable, standardised, numbered, and replaceable. Being made of metal—Duralumin—they combine great strength with very light weight. They are untarnishable, and can be immersed in sterilizing fluid without injury. They can be used repeatedly.

Invaluable for

Hospital Emergency work, particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

116, Victoria Street, Westminster, LONDON, S. W. 1.

HARROGATE

is one of the finest SPAS and HEALTH and PLEASURE RESORTS in EUROPE.

AS a HEALTH and PLEASURE RESORT it is famed for its remarkably pure and bracing air, its fine shops and residences, its open spaces, parks, high-class amusements and entertainments, and last, but not least, its ideal situation as the centre of some of England's most glorious countryside.

As a SPA it claims supremacy over all the Spas of the world by virtue of having no fewer than 23 different mineral waters, and a most elaborate and completely equipped Bathing Establishment, with a Staff of upwards of 200 Medically Trained and Medically Certificated male and female Nurses. It is really a compendium of the World's Spas.

Cases treated with benefit comprise:

(1) Gout and other metabolic disorders (glycosuria, obesity).
(2) Functional liver derangement and early cases of cirrhosis, cholelithiasis, and cholecystitis.
(3) Chronic skin diseases of all kinds.
(4) Synovitis, fibrositis, sciatica, and other forms of neuritis.
(5) Arthritis (rheumatoid, chronic rheumatic, and toxæmic varieties).
(6) Mucous colitis, chronic dysentery, constipation, and intestinal toxæmias.
(7) Anæmia in its various forms.
(8) Nervous diseases (neurasthenia and hysteria).
(9) Hyperpiesis.
(10) Sequelæ of tropical diseases, especially anæmia.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairtechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

HAYDOCK LODGE
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1930.

The Senate announce the following vacant External Examinerships for all Examinations above Matriculation for the year 1930. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included.

The Examiners for the Final Examinations will be invited as occasion arises to take part in the Higher Examinations, but the Senate have resolved that in certain cases in which the work is heavy they shall not be required to do so.

For the First Examination for Medical Degrees.
Biology. Chemistry. Physics.

For the Second Examination for Medical Degrees
Anatomy (two). Pharmacology. Physiology.
NOTE.—One of the two Examiners appointed in Anatomy will be required to act for Science Examinations also.

For Final and Higher Examinations for Medical Degrees.
Medicine. Surgery (two). State Medicine.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GLD. P. GODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable on or before Monday, July 7th, 1929. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

Applications are invited from male registered practitioners for the combined post of Assistant County Medical Officer of Health and District Medical Officer of Health.

The duties of the post include medical inspection of school children, maternity and child welfare work, clinical and tuberculosis work, and general public health work. The possession of the Diploma of Public Health is essential. The person appointed will be required to devote the whole of his time to the services of the two Councils.

The total salary will be £625 per annum; motor car allowance will be paid according to the County Council's scale for the use of the Officer's car.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund. The appointment will be terminable by three months' notice on either side.

Applications must be made upon a form to be obtained, together with further particulars, from the County Medical Officer of Health, County Hall, Ipswich, to whom the completed forms should be returned not later than Friday, July 12th.

County Hall, Ipswich. CECIL OAKES, Clerk of the County Council.
June 14th, 1929.

County Borough of West BROMWICH.

SECOND ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications for the above appointment.

The officer will be subject to and under the directions of the Medical Officer of Health.

The officer appointed will be required to assist chiefly in School Medical and Maternity and Child Welfare Services, and generally to work as one of the Assistants to the Medical Officer of Health.

Experience in Ante-natal work, Diseases of Children, and in the Diagnosis and Treatment of Tuberculosis will be specially considered.

Applicants must be registered medical practitioners and possess a Diploma in Public Health or similar qualification.

The person appointed will be required to devote the whole of his time to the duties assigned to him by the Council, to live in the Borough, and not to engage in private practice.

Salary £600 per annum. No bonus. Appointment terminable on the part of the officer by one month's notice.

Applications (on forms supplied by the undersigned), stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, should be forwarded by not later than July 6th, and should be endorsed "Assistant Medical Officer of Health."

Town Hall, West Bromwich. ALFRED WICKHAM, Town Clerk.
June 19th, 1929.

County Borough of Gateshead.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER AT MENTAL HOSPITAL.

Applications are invited from registered medical practitioners (male) for the post of Assistant Medical Officer at the Gateshead Mental Hospital, Stannington, Northumberland.

Applicants must not be over 35 years of age and should have held a resident appointment in a General Hospital.

The salary will be at the rate of £400 per annum, rising by increments of £25 to £500 per annum, with board, lodging, and laundry (valued at £150 per annum), and will be subject to deductions according to the Asylum Officers Superannuation Act of 1909. The appointment to be terminable on three months' notice from either party.

The successful candidate will be expected to obtain the Diploma in Psychological Medicine.

Preference will be given to candidates having experience in Ear, Nose, and Throat Diseases.

Applications, accompanied by copies of three recent testimonials, to be sent to the Medical Superintendent, Gateshead Mental Hospital, Stannington, Northumberland, not later than Friday, July 12th.

Personal canvassing will be a disqualification.

By Order,
W. SWINBURNE,
[illegible] Town Clerk.
[illegible] Clerk to the Visiting Committee.
[illegible], 1922.

County Council of Durham.

MATERNITY AND CHILD WELFARE.

ASSISTANT WELFARE MEDICAL OFFICER.

The County Health Committee invite applications for the appointment of an Assistant Welfare Medical Officer (woman) at a commencing salary of £600, rising by annual increments of £25 to £650 per annum. Travelling expenses will be paid by the County Council according to scale.

Applicants must be registered medical practitioners of not less than three years' standing, and not exceeding 45 years of age, with special experience in Maternity and Child Welfare work and its organization. The person appointed will be required to reside in Durham City or other approved centre, and to devote her whole time to the duties of the office, and must be prepared, if called upon, to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer, and will be debarred from engaging in private practice. The D.P.H. or its equivalent will be considered an additional qualification.

The appointment will be terminable by three months' notice on either side.

A condition of the appointment is that on marriage the officer will be required to vacate her post.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical examination, as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, marked "Assistant Welfare Medical Officer," together with copies of not more than three recent testimonials, must be sent to the County Medical Officer, Shire Hall, Durham, not later than the 27th instant.

Shire Hall, Durham. HAROLD JEVONS, Clerk of the County Council.

June 14th, 1929.

Walsall and West Bromwich UNIONS JOINT COMMITTEE.

GREAT BARR HALL and GREAT BARR PARK COLONY.

APPOINTMENT OF ASSISTANT RESIDENT MEDICAL OFFICER.

The Committee invite applications from fully qualified resident medical practitioners for the appointment of Assistant Resident Medical Officer for the Institutions at Great Barr Park. The Institutions consist of Children's Homes for approximately 100 children under the age of five years and a Mental Defective Colony. The number of patients at present at the Colony is approximately 300. This number will be increased to 600.

The Assistant Resident Medical Officer will be responsible to the Resident Medical Officer, who in turn will be responsible to the Visiting Consulting Mental Officer so far as the Children's Homes are concerned, and a Visiting Consulting Medical Officer attends when required at the Colony.

Salary £200 per annum, together with furnished quarters, rations, laundry, and attendance.

The officer appointed must devote the whole of his time to the duties, and the appointment will be terminable by three months' notice on either side.

Canvassing, either directly or indirectly, is strictly prohibited and will be deemed a disqualification.

Applications, stating age, experience, and qualifications, accompanied by copies of not more than three recent testimonials, must reach me not later than Saturday, June 29th.

By Order,
A. H. WARD, Clerk.

22, Lombard St., West Bromwich.
June 12th, 1929.

County Borough of Ipswich.

The Council invites applications for the post of ASSISTANT MEDICAL OFFICER at the SANATORIUM (120 beds). Candidates must be unmarried, not exceed 30 years of age, registered, and qualified to practise Medicine and Surgery in England. Preference will be given to a candidate who has held the post of H.P. at a recognized Hospital for Diseases of the Chest. The appointment is for a period of six months in the first instance, but may be extended at the end of that time. Commencing salary will be at the rate of £250 per annum, with board, residence, and laundry. Further particulars can be obtained from, and letters of application, stating age, qualifications, experience (if any), and accompanied with copies of two recent testimonials, should be sent to W. F. SUTCLIFFE, Medical Superintendent, Ipswich Sanatorium, Suffolk, on or before June 29th.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified medical practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital, Birmingham.

The Hospital has 926 beds, divided into Medical, Surgical, Children's, Infectious, Maternity, Gynæcological and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that period.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Chief Medical Officer, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salaries and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum. Fourteen days' leave will be granted to the successful candidates during their terms of office.

Further particulars of the appointments may be obtained from the Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than Thursday, July 4th.

Union Offices, Birmingham. C. P. BEECH, Clerk to the Guardians.

June 17th, 1929.

Administrative County of Essex.

APPOINTMENT OF MALE ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered medical practitioners specially qualified in the treatment of Tuberculosis, School Medical Inspection, and Maternity and Child Welfare, holding a Diploma of Public Health, and not over 45 years of age.

Preference will be given to candidates who have had at least three years' experience in Public Health work subsequent to their medical qualification. The salary attached to the appointment will be £600 per annum and travelling expenses. The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to reside in such district of the County as the Council may decide. The appointment will be subject to three months' notice on either side.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Monday, July 1st.

Shire Hall, Chelmsford. JOHN H. GOOLD, Clerk of the County Council.

June 11th, 1929.

City of Leicester.

MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Health Committee of the Leicester Corporation require the services (whole-time) of a Maternity and Child Welfare Medical Officer and Organizer of Infant Welfare Centres, age not to exceed 40 years. The duties will be those usually appertaining to such a post, including the supervision of Health Visitors, Inspection of Midwives and Nursing Homes, conducting Ante-natal and certain Infant Clinics. Ability to address meetings of mothers will be an additional qualification. Commencing salary £600 per annum. The person appointed will be required to contribute to the Corporation Superannuation Fund.

Applications, stating qualifications, age, experience, whether married or single, and accompanied by three recent copies of testimonials, to be sent to the undersigned not later than Wednesday, June 26th.

Health Dept., Leicester. C. KILLICK MILLARD, Medical Officer of Health.

June, 1929.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculosis and venereal diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1923, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Saturday, June 29th. Canvassing, directly or indirectly, will disqualify.

County Hall, Kingston-upon-Thames. DUDLEY AUKLAND, Clerk of the County Council.

June 8th, 1929.

Administrative County of London

The London County Council invites applications for three appointments, as from October 1st, 1929, as PRINCIPAL MEDICAL OFFICER in its Public Health Department. The duties attaching to the positions will be mainly concerned with general public health work; school medical service; infectious diseases; tuberculosis; children's diseases; administration of hospitals, especially Poor Law Hospitals; and district medical work. Each of the officers appointed will be placed in charge of a division of the Department dealing with branches of the work and will be responsible to the County Medical Officer of Health.

The commencing salary in each case will be £2,000 a year, rising by £100 yearly to £2,500 a year. Candidates must be not more than 55 years of age on October 1st, 1929.

Forms of application, containing full details, may be obtained from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. A stamped addressed envelope should be enclosed and forms must be returned by July 3rd, 1929.

Canvassing disqualifies.

MONTAGU H. COX, Clerk of the Council.

Administrative County of London

The London County Council invites applications for appointment, as from October 1st, 1929, as MATRON-IN-CHIEF in its Public Health Department. Candidates must be fully trained nurses and must have administrative experience of hospital nursing. The principal duties attaching to the position will consist in organising and supervising the nursing staff of the hospitals which will be transferred to the Council under the *Local Government Act*, 1929. The total commencing salary will be £750 a year, rising by £50 a year to £1,000 a year. Applicants must be not more than 55 years of age on October 1st, 1929.

Forms of application containing full details may be obtained from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. A stamped addressed foolscap envelope should be enclosed. Forms must be returned not later than July 3rd, 1929. Canvassing disqualifies.

MONTAGU H. COX, Clerk of the Council.

Cumberland Education COMMITTEE.

APPOINTMENT OF ASSISTANT DENTAL OFFICER.

The Committee invite applications for the above post (male or female). Applicants must be fully qualified Dentists. Salary £450, rising to £500 by two annual instalments (subject to deductions under the provisions of the L.G.O.S. Act), with allowance for travelling and subsistence while on duty.

Particulars and forms of application on receipt of stamped addressed foolscap envelope addressed to "The School Medical Officer, County Offices, Carlisle."

C. W. ALLAN HODGSON, Clerk to the Committee.

June 3rd, 1929.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	12th and over
	(ii) During 24th and 25th years' service	1500		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 6th August, 1929.

Manchester Union.

ASSISTANT MEDICAL OFFICER.

The Guardians of the Manchester Union invite applications from medical practitioners who have had previous resident Hospital experience for the following appointments:

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER (male) at the WITHINGTON HOSPITALS (1,200 beds) and INSTITUTION (1,150 beds), Nell Lane, West Didsbury, Manchester;

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER (male) at the CRUMPSALL INFIRMARY (1,300 beds) and INSTITUTION (1,600 beds, including 600 beds for Mental Patients), Crescent Road, Crumpsall, Manchester.

The Hospitals and the Infirmary are recognized Training Schools for Nurses and are equipped with all modern Hospital requirements.

The appointments are entirely separate and the salary for each will be at the rate of £275 per annum, with rations and furnished apartments, subject to the usual deductions under the Poor Law Officers' Superannuation Act, 1896.

The successful candidates will be required to commence duty on September 1st.

Applications, endorsed "Medical Appointment," stating at which establishment—Withington or Crumpsall—an appointment is desired, accompanied by not less than three testimonials, must reach me not later than Wednesday, July 3rd proximo.

Candidates desiring to apply for more than one appointment must send in a separate application in respect of each Hospital.

By Order,
F. W. GREENHALGH,
Clerk to the Guardians.

Union Offices, All Saints, Manchester.
June 13th, 1929.

County Borough of Barnsley.

MEDICAL OFFICER OF HEALTH.

The Barnsley County Borough Council invite applications for the positions of Medical Officer of Health, School Medical Officer, Chief Tuberculosis Officer, Infant Welfare Superintendent, and Chief Officer of the Corporation's Venereal Disease Clinic. The total commencing salary for the whole of the positions held will be £900 per annum. Candidates must be duly qualified medical practitioners, possessing a recognized Diploma in Public Health and the requisite qualifications required by Acts of Parliament and the Regulations of the Ministry of Health, in respect of each of the above positions. The gentleman appointed will be required to devote the whole of his time to his duties and will not be allowed to engage in private practice. Canvassing, either directly or indirectly, will be regarded as a disqualification, but the selected candidates will be permitted to send 20 copies of their application and testimonials for use of members of the Selection Committee. Applications, accompanied by copies of not more than three recent testimonials, must be sent to the undersigned, endorsed "Medical Officer of Health," not later than Monday, July 8th.

A. D. MASON,
Town Clerk.

The Town Clerk's Office, Barnsley.
June 12th, 1929.

The Royal Albert Hospital and EYE INFIRMARY, DEVONPORT.

A vacancy for an ASSISTANT HOUSE SURGEON (unmarried) exists. Applicants must be fully qualified, registered, and the appointment will be for six months. Salary £50 per annum, with apartments, board, and laundry free.

Applications, stating age, accompanied by copies of not more than three testimonials, should reach the undersigned not later than Friday, June 28th.

By Order of the Committee,
FRANK ROWE,
Secretary.

June 3rd, 1929.

The County Hospital, York.

Applications are invited for the post of HOUSE SURGEON. Salary £150, with board-residence, etc. Duties begin August 1st. Applications, stating qualifications and experience, should be addressed to the undersigned, to arrive not later than June 30th.

J. BIRBECK, Manager.

The County Hospital, York.

Applications are invited for the post of ASSISTANT ANÆSTHETIST, who will also be required to assist the House Surgeon. Salary £150, with board-residence. Duties begin about July 14th. Applications, stating qualifications and experience, should be addressed to the undersigned, to arrive not later than June 30th.

J. BIRBECK, Manager.

Metropolitan Asylums Board.

TUBERCULOSIS SERVICE.

APPOINTMENT OF CONSULTING LARYNGOLOGIST.

The Board desire to obtain the services of a Consulting Laryngologist for their Institutions for the treatment of Pulmonary Tuberculosis. Remuneration at the rate of 200 guineas per annum, but it is possible that the work may be divided between two Consultants at a remuneration at the rate of 100 guineas each. Visits to be made once a month to four Institutions, and once every two months to two Institutions. Three of the Institutions are situated in the outer suburbs of London, and the other three are near Godalming, Wokingham, and Brentwood respectively.

Form of application, giving full particulars, may be obtained by forwarding stamped addressed foolscap envelope to the Clerk, Metropolitan Asylums Board, Victoria Embankment, London, E.C.4, to whom completed applications must be returned not later than 10 a.m. on Thursday, July 4th.

ALLAN POWELL, Clerk to the Board.

Metropolitan Asylums Board.

The Board invite applications for appointment as JUNIOR ASSISTANT MEDICAL OFFICER in their Mental Hospitals Service. Salary £500 per annum, rising after three years' approved service to £560. Candidates must be under 40 years of age, and should hold, or should be prepared to undertake to read for, the Diploma in Psychological Medicine. The appointment is renewable annually, and is made in the first instance to March 31st, 1930.

If the candidate appointed is required to reside in the Institution to which he is allocated, a charge fixed by the Board's Finance Committee will be made for such residential allowances as may be authorised.

Forms of application may be obtained by sending stamped addressed foolscap envelope to the Clerk to the Board, Metropolitan Asylums Board, Victoria Embankment, E.C.4, to whom they should be returned not later than July 4th.

ALLAN POWELL, Clerk to the Board.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Westo—London. Telephone: Mayfair {1783 / 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Splendid educational facilities and unlimited sport. Scope for surgery.
28. PARTNERSHIP.—LONDON.—*In a populous district, the half share of* an old-established middle and working-class Practice, worth over £2,000 p.a., including panel of 1,300 Visits 3/6 to 10/6. Expenses light, car not necessary. House contains professional accommodation, 2 reception, 2 bedrooms, bathroom, etc. Held on lease at rental of about £60 p.a. Premium 2 years' purchase.
29. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the *F.R.C.S. degree.* Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

CLEAN UP
THE INTESTINAL TRACT

TOXÆMIA

IS AN IMPORTANT FEATURE
IN A WIDE VARIETY OF CASES.

HEADACHE–INSOMNIA–DEPRESSION

CHRONIC AUTO-INTOXICATION plays an important part in many common complaints. Toxæmia of intestinal origin is the basic difficulty in most cases of the type mentioned above. Laboratory examination of the fæces generally shows an abnormal number of B. coli, staphylococcus, putrificus and streptococcus.

The B. Acidophilus, always present in the healthy bowel, will be found to be very few or almost entirely absent. The reimplantation of B. Acidophilus by oral administration transforms the intestinal flora; overcomes intestinal putrefaction; re-establishes adequate normal defæcation, with the resultant disappearance of the unpleasant symptoms. The most economical and efficient form of acidophilus therapy is

B. ACIDOPHILUS EMULSION

which overcomes toxæmia of intestinal origin and promotes normal adequate defæcation.

SEVENTH EDITION. NOW READY.

HERMAN'S DIFFICULT LABOUR

A Guide for Students and Practitioners

Revised by CARLTON OLDFIELD, M.D. Lond., F.R.C.S. Eng., F.R.C.P. Lond.

This medical classic has again been carefully revised by Mr. Carlton Oldfield.

New chapters dealing with the Prevention of Puerperal Sepsis and the Mitigation of Pain in Labour have been added, and the chapter on Albuminuria of Pregnancy and Puerperal Eclampsia has been rewritten.

A feature new to this edition is the introduction of eight radiographic plates illustrating various abnormal obstetric conditions.

574 pages, Crown 8vo. With 8 Radiographic Plates and 197 Illustrations in the Text. 16s. net.

NINTH EDITION.

MANSON'S TROPICAL DISEASES

Edited by PHILIP H. MANSON-BAHR, D.S.O., M.A., M.D., D.T.M. & H.Cantab., F.R.C.P.Lond.

Every chapter of this famous work has been thoroughly revised, and many parts of the book have been rewritten. The illustrations have been reinforced by the addition of nine new plates and some thirty new text-figures.

"A clear, accurate, and up-to-date account of the present position of tropical medicine."—BRITISH MEDICAL JOURNAL.

942 pp., Demy 8vo. 23 Colour and 12 Half-Tone Plates, 401 Illus. in Text, 6 Maps & 34 Charts. 31s. 6d. net.

THE ESSENTIALS OF MEDICAL DIAGNOSIS

A Manual for Students and Practitioners

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P.Lond., and A. E. GOW, M.D., F.R.C.P.Lond.

This Manual consists of concise descriptions of the methods of investigating cases of disease in the manner actually carried out in practice.

"Well written and thoroughly practical."—BRITISH MEDICAL JOURNAL.

"A successful attempt to relay the foundation-stones of the art of diagnosis."—LANCET.

702 pp., Crown 8vo. 8 Colour and 11 Black-and-White Plates, and Figures and Charts in Text. 16s. net.

SEVENTH EDITION.

ELEMENTS OF SURGICAL DIAGNOSIS

By Sir ALFRED PEARCE GOULD.

Revised by ERIC PEARCE GOULD, M.D., M.Ch.Oxon., F.R.C.S.Eng.

This Manual has been subjected to a careful revision and is now once more abreast of the knowledge upon which the diagnosis of surgical conditions is based.

"The seventh edition is worthy of even greater success than has attended the previous issues."—BRITISH MEDICAL JOURNAL.

SIMPLIFIED RADIOGRAPHY

UNTIL the advent of the "METALIX-PORTABLE" the introduction of X-rays in general practice was admittedly a matter for thought. Of the difficulties we are aware, because PHILIPS engineers have studied them. That is why they have made this problem peculiarly their own. By dint of careful research and sound design all the old objections have been successfully overcome. The result is a revelation. With the "METALIX-PORTABLE" any medical man can make excellent radiograms without previous experience. At the patient's house or in the consulting room, this apparatus can be easily conveyed and operated from any convenient light socket. There is an entire absence of danger. Both patient and operator are alike protected. The "METALIX" principle of construction is a sure safeguard against unwanted radiation, whilst in addition the entire apparatus is absolutely shockproof.

We shall be pleased to send you full particulars, or, better still, arrange a demonstration.

WINDOW HYGIENE IN CITIES

Permanent inlet for ultra-violet rays created by "Vita" Glass

Natural ultra-violet radiation is available in cities and in the smoke-charged atmosphere of industrial localities. Recent research has afforded unimpeachable evidence that an appreciable amount of ultra-violet light penetrates to such areas, but it is shut out of city buildings by windows of ordinary glass.

"Vita" Glass renders every window that receives direct daylight permanently hygienic, whether the window faces North, South, East or West, in Summer or Winter.

"Vita" Glass creates in perpetuity an inlet for the ultra-violet rays, and can prove of great assistance to the practitioner in the treatment of patients who cannot be moved out of doors.

The installation of "Vita" Glass is not a costly matter to-day. For instance, a bay-window of average size can be fitted with "Vita" Glass for 38/-, plus the cost of fixing.

Further information about "Vita" Glass will be sent to any Medical man who is interested. Write to: "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

SURGICAL SERVICE
SALTAIR

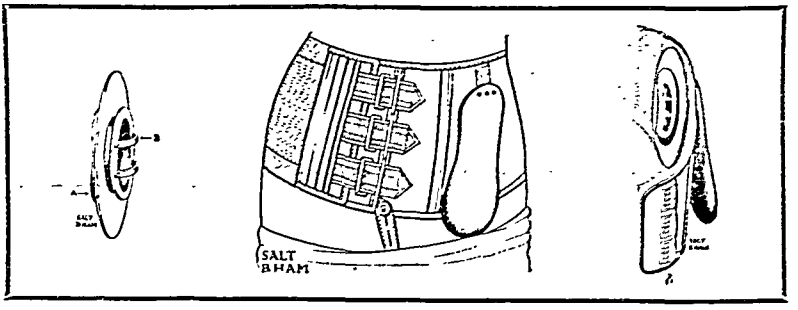
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

SALTS' PATENT COLOSTOMY BELT



The fact that many Hospitals and Surgeons are now prescribing Salts' Patent Colostomy Belt and the vast increase in Repeat Orders goes to prove, conclusively, the efficiency of this up-to-date Salt appliance.

ADVANTAGES

1. Detachable receiver sterilizable by boiling.
2. Mouth of bag kept open for free entry of fæces.
3. Easy removal and cleaning of bag, without removal of belt.
4. No crevices to hold fæces, and therefore little odour.
5. Less bulk, greater comfort, and more sanitary than any other.
6. Rubber portions far more durable than in the old style belt.

Spare Bags are easily and quickly obtainable at low cost.

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

OVALTINE

FOR INSOMNIA.

Sleeplessness is a common feature of Neurasthenia. The value of "Ovaltine" in this condition is exceptional. A cup of "Ovaltine" taken upon retiring allays nervous irritability, and the patient passes into a natural and healthful sleep.

As evidence of the value of "Ovaltine" in Insomnia the following extracts from unsolicited medical reports are noteworthy:

"The patient slept the first night I used 'Ovaltine,' but I thought it merely a coincidence. By continuing its use, however, I am convinced of the value of 'Ovaltine' to induce sleep."

"In a case of Neurasthenia associated with sleeplessness and difficult feeding I gave my patient 'Ovaltine.' To my great satisfaction 'Ovaltine' was retained without difficulty, and rapid improvement followed."

"Ovaltine" is a rich concentration of the vitalizing principles of malt, milk, and eggs. Its delicious flavour and its high nutritive and digestive qualities render it a food beverage of outstanding worth.

A liberal supply for clinical trial sent free on request.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

In Hyperchlorhydria

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

and other conditions of gastric over-acidity, Alka-Zane will afford prompt relief from distressing symptoms and restore normal alkaline balance.

Diuretic and antacid, Alka-Zane is indicated wherever the alkali reserves are unduly depleted, as in intestinal disturbances, rheumatic affections and certain anaphylactic manifestations.

ALKA-ZANE

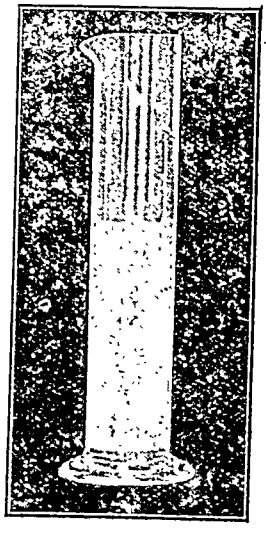
The 'Allenburys' DIET

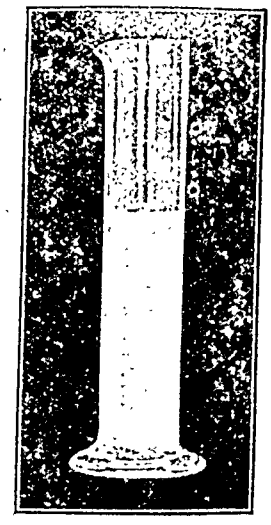


A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk.

A Stimulating and Sustaining Food Beverage

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.

ALLEN & HANBURYS LTD., Bethnal Green, London, E.2.

INFANT FEEDING—a vital problem to the Medical Profession

If you have any difficult cases of infant feeding, will you permit us to send you samples sufficient to prove the outstanding merits of Humanised Trufood? It is the nearest approach to breast milk yet achieved, and this has been proved by every test known to science.

BECAUSE we know that every Doctor is interested in the problem of infant feeding, we submit below further record of the good results Humanised Trufood is achieving in other doctors' practices.

169, Church Street,
Woking, Surrey.

"I feel it my duty to let you know what Humanised Trufood has done for our baby girl. She weighed only 3½ lbs. at (Premature) birth, and was so tiny she was fed with a fountain pen filler, just a few drops of whey at a time. She was kept in cotton wool for nearly two months. She was put on Humanised Trufood, and it worked wonders. She is now nine months old, has six teeth, and is a real bonny baby. We are starting her on Trufood Full Cream. Baby's weight is now 15¾ lbs., so you will know how she has progressed.

Yours faithfully,
(Signed) C. COBBETT."

In the treatment of

Syphilis

BISOXYL

The ready absorption of Bisoxyl causes the rapid destruction of spirochætes; moreover, the injection is painless and gives rise to no complications.

Bisoxyl may be used alone or in conjunction with arsenobenzene preparations.

Experience has shown that the type of lesions characteristic of syphilis will respond to bismuth treatment even when other drugs have failed. It is of the utmost importance, however, that the bismuth suspension is properly prepared and is in an extremely fine state of sub-division. Bisoxyl fulfils completely these essential conditions, and its administration has been followed by marked success.

Local Anæsthesia in Surgical Practice

EXCISION OF TUMOUR.

Typical Case.

H. M., aged 8 years.

Diagnosis: Hæmangioma of right arm.

Operation: Excision of the tumour.

Anæsthesia: Local infiltration.

History: Since birth the patient had presented a tumour on the anterior aspect of the right arm. The tumour was approximately 20 cm. in length and 8 cm. in width, and fluctuated.

Operation: A circular infiltration block was made above the tumour, the needle being introduced directly toward the humerus until the growth was practically isolated from its nerve supply, 120 c.c. of 0.5 of 1 per cent. Novocain-Adrenaline solution being used. An incision 20 cm. long was made and the tumour dissected out. It arose from the attachment of the deltoid to the humerus in front of the biceps, from which it could be peeled, but its attachment to the deltoid was so intimate that a portion of this muscle had to be removed with the tumour.

NOTE.—This child laughed throughout his operation and enjoyed every moment of it.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

In view of the increasing use of Monsol in clinical practice both in this country and overseas, the following list of standard dilutions has been prepared for the assistance of the Medical Profession:

As an ordinary antiseptic Dressing:—	*1 teaspoonful Monsol to 1¼ pints water (1-200).*
Vaginal Douches and Irrigations:—	*1 teaspoonful Monsol to 3 pints water, gradually increasing to 2 teaspoonfuls Monsol to 3 pints water (1-500 to 1-250).*
Tampons:—	*1 to 2 tablespoonfuls Monsol to ½ pint water (1-20 to 1-10).*
Aerial Spray:—	*1 teaspoonful Monsol to ½ pint water (1-80).*
Packings:—	*1 tablespoonful Monsol to ¼ pint water (1-20).*
Instruments, etc.:—	*1 tablespoonful Monsol to ½ pint water (1-20).*
Irrigation & Dressing of Septic Wounds:—	*1 tablespoonful Monsol to 1¼ pints water (1-50).*
In the Sick Room:—	*In all water for washing, for cleaning bedroom vessels etc., 1 tablespoonful Monsol to 2 quarts of water (1-160).*
Nasal Spray, or Throat Gargle or Mouth Wash:—	*6 to 8 drops Monsol in ½ tumbler of water (about 1-800).*
Cuts, Abrasions, Sores, Stings, etc.:—	*1 teaspoonful Monsol to 1 pint (1-160).*
Midwifery Cases:—	*1 teaspoonful Monsol to 1 pint (1-160).*
In the Bath:—	*1 teaspoonful to a bath full of water.*
Rectal Douching:—	*1 teaspoonful Monsol to 1 pint (1-160).*

THE MOND STAFFORDSHIRE REFINING CO. LTD, ABBEY HOUSE, WESTMINSTER, S.W.1

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat."

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition :—

	Dry Food	Reconstituted (1 part in 8 parts of water)
Fat	15.5	1.7
Proteins	20.0	2.2
Lactose	58.0	6.4
Mineral Matter	4.5	0.5

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply Samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods.

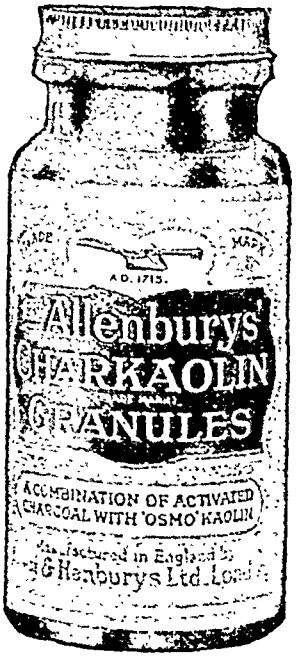
The 'Allenburys'



'CHARKAOLIN' GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

Pernicious Anæmia

TRADE MARK 'WELLCOME' BRAND
LIVER EXTRACT

(An Active Selected Fraction of an Extract of Fresh Liver)

Prepared by a process tested and found efficient by the Medical Research Council.

Clinical reports continue to present evidence of the prompt response to the administration of 'WELLCOME' LIVER EXTRACT in pernicious anæmia.

Liver treatment is valuable in cases of secondary anæmia due to hæmorrhage, such as hæmatemesis or post-partum hæmorrhage. Also suggested in conditions due to liver dysfunction and in the vomiting of pregnancy and pre-eclamptic conditions.

In tubes, each containing an active selected fraction of an extract derived from half-a-pound of fresh liver.

DIRECTION.—The contents of one tube, or more, daily, in soup or water, or as directed by the physician.

Supplied at 3/- per tube, and in boxes of 12 tubes at 35/- per box

UPPER PORTION OF ONE OF THE GATEWAYS OF A *STŪPA*.—One of the most perfect and beautiful of the monuments produced by the early pioneer architects and sculptors of India. It is interesting to observe that the structure virtually represents carpenter's work carried out in stone—a bold undertaking. The gateway rests upon two square pillars, four metres high, surmounted by immense capitals decorated with elephants, which, in their turn, support three slightly curved lintels. The entire structure is decorated with a wealth of splendid bas-reliefs, illustrating the legendary scenes in the lives of the Buddha. This, with the other three gateways of the *stūpa*, might indeed be said to constitute the Buddhist Bible; moreover, together with the mysteries embodied in the whole structure of the *stūpa*, it provides a record of the religion, thought and life of India from the earliest times. Crowning the summit is a fragment of the sacred "Wheel of the Law" resting upon the backs of four elephants; two worshippers, of which one remains, stood one on either side. It was not permitted to portray the person of the Great Teacher; his presence is indicated by symbols—the bodhi-tree, two footprints, a throne of stone, the Sacred Wheel, and others.

High Blood Pressure

(Hyperpiesia)

A Man is as Old as his Arteries

Postulate 1.

Let it be granted that the intestine daily contains large quantities of toxic substances from the decomposition of food by bacteria.

Postulate 2.

Let it be granted that the absorption of these toxins must result in *diminished resistance,* or loss of control of the natural defences of the tissues generally and the circulatory system in particular.

Postulate 3.

Let it be granted that these toxins present in the blood are conducive to all the symptoms and signs associated with high blood pressure.

Then it can be demonstrated that *treatment for permanent improvement* of persons suffering from high blood pressure must include some form of daily intestinal disinfection to control the manufacture of 'pressor' toxins.

Q. E. D.

Dimol does this effectively*

It has a Rideal-Walker Co-efficient of 35.

It is absolutely non-toxic and does not find its way into the circulation.

It can be given over prolonged periods without any deleterious effects on the intestinal mucosa.

**Clinical evidence will be sent to any Medical Practitioner on application to the*

Remarks on THE PRESENT POSITION OF THE PROBLEM OF PSYCHIATRIC PATHOLOGY.*

BY

W. F. MENZIES, M.D.ED., F.R.C.P.,

CHEDDLETON.

THE mental case is too often an unwelcome addition to the anxieties of the busy practitioner. Apart from nursing difficulties the whole process of ingravescent mental disorder seems to him so ill-defined, even mysterious, that he scarcely knows where to begin. He finds it far from easy to persuade the relatives that early removal to a special hospital is desirable, although he assures them that thus only can the patient receive proper treatment. This is a most generous attitude on his part, for he knows that, except for moral control and outdoor exercise, the case will receive much the same symptomatic treatment as he himself is well able to supply—chiefly laxatives and sedatives. But it is undesirable that any case of illness should present itself to a medical man as a nuisance, and for this those who practise and teach psychiatry are largely to blame. *The limited time available in a crowded curriculum* precludes the teacher from directing the attention of the senior student to the physiological and neurological aspects of mind, so that, coming fresh from more exact histological and biochemical laboratory methods, he is given "nothing to get hold of." We may as well admit our ignorance—we cannot teach what we do not know; for, let there be no doubt about it, theories of the causation of mental illness are highly problematical. But the best way to tackle a problem is to set up a theory and then proceed to demolish it, until from the ruins a sounder edifice can be erected. There are no mental diseases properly so called, there is only disordered action of the brain cortex; there is no essential difference between the neuroses, the psychoneuroses, and the psychoses; *the diseased processes which* result in mental illness are just those which we are accustomed to recognize in physical disorders, and that the clinical presentations are so different is more a social than a medical problem. Therefore I believe that the general practitioner could help the psychiatrist beyond measure if he had time to make a note on his clinical cases of all the slight mental changes which occur from day to day—the attitude, facial expression, mental outlook expressed in conversation, memory, attention, interests, dreams, reaction to pain, and so on, carefully correlated to the somatic signs present. This address is frank propaganda; its object is to seek the help of our medical colleagues in furthering the great cause of mental welfare, one important aspect of which is the pathology of mental disorder. It may enlist their interest if I mention a few of the almost innumerable problems upon which we should like light to be thrown. These are not selected quite at random, but because over forty years of clinical experience suggest to me that some of them may ultimately yield useful results in furthering the cause we have at heart.

The efforts of Pinel, Tuke, Conolly, and others at the beginning of last century and earlier were devoted to the social amelioration of the insane rather than to the scientific side, so that France and England lagged behind Germany; nor had the United States, where of late years more work has been done than anywhere else, yet entered the lists. But for nearly a century a long roll of distinguished workers in the Wakefield Asylum laboratory has kept alive the spirit of research—Sir William Ellis, Sir David Ferrier, Dr. Henry Maudsley, Sir James Crichton-Browne, Dr. Herbert Major, Professor Bevan Lewis, and the present president of the Royal Medico-Psychological Association, Professor J. Shaw Bolton. Nowadays, of course, nearly every mental hospital and psychiatric clinic has its laboratory, and, especially since 1918, an enormous stream of literature has poured forth, applying to mental cases nearly every clinical or laboratory test which has been suggested for use in general medicine. And withal I think we must confess that no special light has been thrown upon the genesis of mental disorder. Not that all these efforts have been wasted; on the contrary, a negative deduction is of value in eliminating one more source of error.

Within the last two years the Royal Medico-Psychological Association, recognizing that one great reason for failure has been diffusion of effort, and that more and more in the future team work will be necessary, has, mainly through the enthusiastic drive of one of our recent presidents, Colonel J. R. Lord of Epsom Mental Hospital, appointed a comprehensive committee to co-ordinate investigation. We do not expect miracles, we realize that none of those at present alive are likely to see a solution of our difficulties, but we do at least hope to make a beginning, to build up effort gradually, until in the end some such body as the Medical Research Council, or even the League of Nations, takes up the work. But right at the beginning it seems to me that it would be a mistake to start with such abstruse problems as schizophrenic conditions: we are more likely to advance by means of the simpler emotional and toxic psychoses. It is true that the lamented death of Sir Frederick Mott left incomplete his work on dementia praecox and the endocrine glands, but I think he wanted really to establish a standard, for he often expressed to me the hope that biochemical work on the action of the vegetative nervous system in connexion with the emotions would follow upon his anatomical findings. And so I confine myself here to the manic-depressive or toxic psychoses, and suggest a pathology which will serve as well as any other as a cock-shy; for what excites opposition may also, in some corner or other, stimulate investigation.

The mention of the word toxaemia is apt to raise a smile, yet I doubt if anyone questions its importance in disease. Many, perhaps most, families of micro-organisms, aerobic and anaerobic, produce by their life-processes haemolytic or neurolytic non-specific poisons, chiefly in the intestine, but also in mouth, fauces, accessory sinuses, or genito-urinary tract, less often in joints, lungs, or skin. These toxins are normally dealt with by the portal system, principally the liver, but if this barrier fails they may reach any part of the body in the blood stream. Before they can affect the neurones of the central nervous system they must reach the cerebro-spinal fluid through the reticulo-endothelial system of the choroid plexuses, and only then can a psychosis be produced. The actual method of production, as suggested by the work of Marinesco, Mott, and others, seems to be a toxic anoxaemia by inhibition of the neuronal oxidases, so that the state of synaptic resistance is altered and the cortical pathways disorganized, for synaptic resistance is the anatomical basis of all regulated nerve action. But, further, the pathways in the basal ganglia, hypothalamus, and mid-brain are liable to become confused, with disastrous consequences to the vegetative and extrapyramidal reflex systems. And so it may come about that the basic emotional feeling-tone which determines the character of the psychosis may be due, not to any difference in the nature of the original toxaemia, nor to any primary variation in the quality of the endocrine secretions, but only to the manner in which these are influenced by the sympathetic system, and so ultimately to the directional manner in which the built-up emotion is presented to the cortical analysers. Therefore I suggest that five essential fields for research are: (1) the bacteriology of the intestine and accessory sinuses; (2) the proteolytic functions of the liver; (3) the histology of the basal ganglia, mid-brain, and hypothalamus; (4) the influence of toxic agents on the cortex; and (5) the permeability of the choroid plexuses.

BACTERIOLOGICAL PROBLEMS.

Clinically we have a good deal of negative knowledge of toxaemia in the psychoses. We meet sepsis in all its forms in mental hospitals; in fact, the helpless social habits of our patients constitute one of our worst surgical troubles; but we never find a septic infection arousing an acute mental exacerbation in a chronic case. I have never seen an acute puerperal psychosis arising primarily in a mental hospital confinement—that is, in a patient already

* Made at a meeting of the Staffordshire Branch of the British Medical Association, May 15th, 1929.

under treatment for some delusional or chronic mental illness. We all know that in a very small percentage of cases of almost any bodily disorder, exanthematous or otherwise, a psychosis may arise, and this quite independently of the degree of severity of the illness. On the other hand, many diseases have their specific mental side, such as thyroid imbalance or pellagra. That toxaemia has a very real connexion with the psychoses is indicated by the improvement when sources of sepsis are removed, especially by a course of autogenous vaccines. Some pathogenic organisms are highly virulent, and produce a toxin demonstrable by a specific reaction, but most intestinal groups are of low virulence, and produce mixtures of non-specific ptomaines whose influence on the host varies extraordinarily under different conditions of susceptibility, etc. This at once suggests some abnormal deviation in a group normally indigenous to the bowel.

At Cheddleton Major F. H. Stewart, working with aerobic methods, has studied the formation by coliforms of phenol and tyramine from tyrosine, and has established the following position.

1. Carriers of N.L.F. coliforms (paracolon mutabile) are four times more common among acute mental patients than among sane controls on the same diet.

2. Bacteria forming phenol from tyrosine in alkaline media are much more abundant in the faeces of acute psychotics than of sane controls; these were chiefly (*a*) the Morgan group (in 25 per cent. of mental cases and 9.5 per cent. of controls), (*b*) *B. phenologenes* of Berthelot—that is, a generic term for any phenol-forming coliform.

3. Fifty per cent. of acute psychotics yielded from faeces in tyrosine media over 0.015 per cent. of phenol; no sane controls reached this amount; many yielded none. Of course, no one supposes that phenol itself is the toxic agent, but it is a mensurable indicator of some more complicated abnormal product.

4. Intravenous autogenous Morgan vaccination will remove this bacillus from the stools without immediate mental improvement, but bodily symptoms may be relieved—that is, headache, dyspepsia, anaemia, loss of weight.

5. In relapsing cases thus treated the place of Morgan in the intestine is taken over by one of the phenologenous group.

Those interested in the subject will find Stewart's work set forth in detail mostly in recent numbers of the *Journal of Mental Science*. What interests us here is not scientific labelling, but solely the question, Does this or that organism produce a toxin? If so, under what conditions, and what is its biochemistry?

Dr. Ford-Robertson at St. Andrew's Hospital, Northampton, has been working on the anaerobic groups, especially the diphtheroid-lepto-streptothrix types, and believes that subtoxic anaerobes play an important part in chronic focal infections, principally in the intestine, but also in teeth, tonsils, sinuses, and cerebro-spinal fluid. Special forms of anaerobes have been found in mental cases which are rare in sane controls, and it would appear that to some groups the central nervous system is especially susceptible.

The work of Dr. F. A. Pickworth, pathologist to the Birmingham Mental Hospitals, is well known from his publications on the bacteriology of the accessory sinuses. Some of his beautifully mounted specimens show bacteria from the sphenoidal sinus passing through the thin bony septum and invading the pituitary fossa and substance of that gland. Many of the patients treated at the Birmingham mental hospitals for sinusitis by Mr. W. S. Adams are stated to have lost their more urgent symptoms—headache, malaise, and depression—and to have been able to return home and resume work.

Finally, in connexion with bacteriological problems, many believe that the organisms actually at fault are filterable viruses, possibly commensal with some which can be readily recovered from the intestine and other body cavities.

Liver Efficiency.

It is not without significance that mental diseases have been associated with liver disturbances since the dawn of medicine; the word melancholia reminds us of the connexion. Clinically a large percentage of recent and acute psychotics show marked digestive upset, chiefly the manic-depressive types, the so-called "toxic" or "toxaemic" class. It is the usual thing for chronic cases subject to periodical acute relapses to usher these in with a "bilious" attack. In recent melancholia we find anorexia, flatulence, gastric discomfort, constipation, often slight jaundice; in early mania, headache, furred tongue, foul breath, or vomiting; all these, of course, are traceable to disturbance of the involuntary nervous system. But there are so many other disorders apart from mental illness which exhibit similar troubles that we want all the information we can get about the emotional side of such functional upsets as seasickness, migraine, vertigo, tinnitus, nystagmus, headache, and the large class of neuroses dubbed "neurasthenia," as well as those included under such headings as "the chronic abdomen." No doubt the intact intestinal mucosa ought to prove an efficient barrier against the entrance of toxins into the portal circulation, but enteroptosis, liver cirrhosis, jaundice, appendicitis, cholecystitis, atheroma, and countless other disorders are evidence of the universality of toxaemia. The functions of the liver are so numerous and ill defined that it is difficult, even theoretically, to devise efficiency tests. The glycogenic function is about the only one which has been seriously attacked in connexion with mental states in this country. S. A. Mann at the Maudsley laboratory, and Drury and Farren Ridge at Stafford, have estimated the blood glucose in a series of cases, and the former in another series used the levulose reaction. Everyone admits that sugar storage is disordered in mental disorder, especially in melancholia, but Mann concludes that the pancreas rather than the liver is at fault. I hardly think his cases were very well selected; what is wanted is not a haphazard group of mental patients, but rather an intensive study of a few cases, correlating the results with the varying mental states. Isabella Robertson has dealt somewhat fully with the homoclasic crisis of Widal, and here again the results are indeterminate, although certainly a leucopenia is much commoner in psychotics than in normal controls. But the connexion of the haemoclasic crisis with liver functions is still undetermined. The various papers of the above workers may be found in the *Journal of Mental Science*, July, 1925. I cannot find any record of a systematic series of van den Bergh reactions in mental cases; it would be trying to the patients to bleed them sufficiently often, and this procedure alone would tend to vitiate results. In some cases at Cheddleton we have obtained encouraging results, but it has only been used where some suspicion of hepatic defect was otherwise excited. It would appear that the efficiency of the liver cells varies from hour to hour, and that the reserve of efficiency is very large. There are some diseases where degeneration of liver and central nervous system occurs simultaneously, such as in Wilson's disease. Also one occasionally, in mental hospitals, meets with cases of pernicious anaemia and subacute combined sclerosis which develop a psychosis, and this may be either excitement or depression.

Mid-brain and Hypothalamus.

Our knowledge of the mid-brain, hypothalamus, and tegmentum is still most imperfect. The parts are not easy of access in the experimental animal, small lesions are misleading and easily fatal, the paths are short and lend themselves badly to degenerations, and the systems are very complicated and not strongly marked. The main connexions of the red nucleus have been fairly well established; it can be studied phylogenetically, and its position as a great co-ordinating centre of extrapyramidal and cerebellar functions is clear. But other grey masses still elude us, and for further advance we must trust to careful records of clinical cases. In this way we are beginning to learn something of two great ganglia—the substantia nigra and the corpus Luysii. It would appear that the neurones of the former are greatly reduced in Parkinsonian degeneration, whatever other centres may be in addition, those of the latter in chronic chorea. Now these two degenerations are associated with somewhat specific mental states. In advanced Parkinsonism euphoria is the rule, although not always seen in early cases. This euphoria is real mental satisfaction and contentment in the patient, and is not merely loss of power over the facial muscles hiding the expression of a dysphoria; the patient enjoys life and entirely fails to realize the gravity of his condition, and a

similar feeling-tone is described in lenticular degenerations. In chorea another change is seen—gross instability of emotional tone. Dr. Pindon Martin[1] has found that nearly all recorded cases show such mental changes and that they are associated with degeneration of the corpus Luysii. Just as in acute chorea the muscular movements are entirely purposeless and belong to a low physiological level, so in chronic chorea the patient is apt to be impulsive, irascible, and uncontrolled. This is well seen in Huntington's chorea, such families being notable for illegitimacy and drink.

The broad view to take of the mid-brain, hypothalamus, and bulb is to look upon the grey masses not so much as nuclei of origin of nerve impulses, but rather as great reflex relay stations between cortical and striothalamic functions; and if it can be shown that different focal lesions are accompanied by uniformly varying feeling-tones the possibility is opened up that emotional variations depend, not so much on the nature of endocrine, sympathetic, and other afferent elements, as on divagations of the paths of presentation to the thalamus, and ultimately to the cortex. The Lange-James theory of the emotions depends upon results produced through afferents from somatic muscle, but we now realize that this is only a small part of the picture, for plain muscle everywhere produces a like effect upon the elements of an emotion. Not seldom one comes across manic-depressive cases whose relapses are sometimes into excitement, sometimes into depression—this from similar sets of causes and without regular sequence. People gravely ill from, say, puerperal or other sepsis vary greatly: some are petulant and fearful, some unreasonably buoyant. And the same occurs in advanced phthisis. Until we know what happens to the sympathetic afferents after they enter the cord, and until we know whether the pain fibres in the posterior columns are unmyelinated or not, it would be premature to formulate definite theories; but if differences in synaptic resistance in the subthalamus and neighbouring parts can be produced by neurotoxins, then the whole mass of glandular, vascular, respiratory, and postural elements which go to build up the complete emotional picture may depend upon geography. Such a line of thought leads straight to Pavlov's theory of sleep; internal cortical inhibitions spreading to the great basal relay stations would remove at once the necessity for predirating a sleep centre in the hypothalamus; synaptic resistances would produce the same effect.

The Action of the Brain Cortex.

The two principal directions in which the human cortex transcends that of lower phylae are the more extensive association areas round each primary centre and the growth of the supragranular layers. Both these have really one objective—the multiplication of neural paths. Supragranular axons are associational only, within the cortex, and each individual path is quite short: infragranular axons form the corticifugal side of the two-way paths to lower nervous levels. The granular layers are, in some sense-reception centres, such as the visuosensory, so numerous as to form a duplicated line, and in final transmitting centres, such as the precentral, so few that the area has been called "agranular." Granule, or stellate, cells are, wherever they occur, the jack-plugs of the switchboard; their dendrites form synapses with the collaterals of distant neurones; their axons break up at once and form synapses with the dentrites of the next neurones in order. They are the actual anatomical means whereby multiplication of neural pathways can be utilized; they are essential elements in the structure of mind. It is sometimes not easy to realize that mind is merely an anatomical arrangement of intensely complicated cortical pathways, and that numerically the neurones can account for all the phenomena displayed. There are a good many platitudes which as neurologists we recognize but as psychiatrists we jib at. Yet there is only one kind of nerve action, whatever it is. A neurone can only discharge, on the "all or none" principle, go through a refractory interval, and slowly recover. There is not one kind of excitation stimulus and another kind of inhibition stimulus: it is all a question of paths. Many years ago Professor McDougall formulated his "neurine" hypothesis, and it has never been improved upon, although possibly he laid too much stress on the passive aspect. Then there is the law of dynamic polarity: the synapses are one-way valves. How they act we know not, but probably it is a matter of slight variations in the hydrogen-ion concentration from moment to moment. Again, serial representation occurs everywhere, as has actually been demonstrated in the visual pathway. So mental images and ideas are slowly built up by repeated experience of different degrees of stimulus. Every concept involves the whole of the nervous system, if only by reference to unconscious memory habits; but not every stimulus causes every neurone to discharge, even in the epileptic fit, the nearest approach to a mass discharge which we know. The convulsion, however, is sufficiently near it to indicate the nature of coma, and, conversely, to suggest that consciousness is a state of receptivity of the cortex to incoming stimuli unimpeded by generalized inhibition, which latter is, as Pavlov points out, sleep. Attention is a directed concentration of neural paths, generally determined by the emotion of the moment. All life is one vast complication of conditioned reflexes at every physiological level, and the unconscious are to the conscious as a million to one. By the law of summation of stimuli repetition lowers the synaptic resistance of a given path, hence instinct, habit, custom. Some paths are biologically very old; thus, the vagus system has altered little since the time of Silurian invertebrates. Other paths are exceedingly evanescent, such as women's dress fashions. Free will is a figment of the imagination; every human action is guided by an almost endless chain of previous conditioned reflexes—biological, racial, hereditary, educational; and the only reason why an experience is never exactly repeated is that life is not long enough. We flatter ourselves that we are guided by reason, but the only difference in mentality between civilized man and savage is that the conditioned reflexes of the latter are on lower physiological levels; they are not guided by recent knowledge, and so we call them superstitions.

Neuro-toxins and the Cerebro-spinal Fluid.

The central branches of the cerebral arteries supply the choroid plexuses, the cortical branches send tiny loops into the surface grey matter of the hemispheres. The cerebro-spinal fluid is secreted by the choroidal epithelium, and to a small extent also is a serous filtration into the perivascular lymphatic spaces of the brain. This latter is not a reversible action within physiological pressure limits. L. H. Weed in America has for many years investigated this matter, following the original work of Dixon and Halliburton; a summary of Weed's views is to be found in *Physiological Reviews*, 1922. Having escaped through the foramina in the roof of the fourth ventricle and reached the cisterna magna the fluid capillarizes up the arachnoid network, chiefly through the Sylvian fissure, over the hemispheres, tends to pool along the great longitudinal fissure, and gradually enters the superior longitudinal sinus, picking up in its course the products of neuronal disintegration. If it is very toxic it may produce death of many supragranular neurones, which is dementia. If the toxicity was prenatal the growing neurones are nipped in the bud, hence amentia. In any case the irritation of the fluid gradually, as age advances, excites the lymphatic hyperplasia which we call the Paccionian bodies. It may be asked why we do not in an acute psychosis necessarily get motor paralyses, blindness, anaesthesia, and other gross lesions. Such a question loses sight of the essential nature of cortical action. The cortex is, after all, only the highest level of the nervous system: its object is an exquisitely delicate selective release; it does not concern itself with the means by which a movement is performed so much as the reasons for that movement. Even if no movement results, the idea of movement, which older psychologists called ideation or conation, is still there. Besides, the toxic injury is only slight: if it were not so, we should get unconsciousness in some form—in other words, coma. We can no more have an active psychosis with a fully paralysed cortex than we can have athetosis with a wholly destroyed pyramidal tract. The lower mechanisms are older and

sturdier, and they are less directly exposed to the wash of a neuro-toxic cerebro-spinal fluid.

The nature of an insane idea may be illustrated by the sign of "past-pointing." Here a lower mechanism, *whether cortical or subcortical*, has by instinct and habit established a conditioned reflex of movement and posture which is presented to the cortical analysers as a composite picture or *schema*, as Head calls it, representing the attainment of a certain position in space arrived at in a certain definite manner. When the lower mechanisms are at fault a different picture is produced, which is again accepted by the cortical analysers at its face value, regardless of the fact that the real value has altered. In the insane idea the composite picture is much more complicated, more largely cortical, each component having its own innumerable subschemes derived from every lower physiological level. Thousands of experiences crowd in from every side of our personality—biological, genetic, instinctive, habitual, educative, social; orderly conduction along the millions of paths which constitute normal reason is disturbed by the toxaemia, and the result reacts upon conduct. The details of the process are infinitely complicated, but the mode of action is fairly understandable in the light of our present knowledge.

It is evident that in health the choroid plexuses form a barrier which prevents deleterious substances—for example, organic arsenical preparations—from entering the cerebro-spinal fluid, but I do not know that there is much experimental evidence concerning permeability to tissue poisons. Büchler[2] of Budapest dealt with the subject, and Walter[3] of Rostock Gelsheim devised a bromide permeability test. Measured doses of sodium bromide are given for five days, and a ratio called the "permeability quotient" is set up between blood bromine and C.S.F. bromine. But probably the P.Q. varies from hour to hour according to blood pressure, serum protein content, buffering, and so on; further, permeability to a crystalloid is no index of the behaviour of the much larger colloid molecule. Nor can we separate out the effects of the accumulation of toxins which produce the acute hallucinations occurring in the endurance trials on American speed tracks after days of continuous driving with practically no sleep from those produced by low oxygen tension, and which result in the depression, confusion, and irritability seen in many from continuous high flying or mountain climbing. The cranium is for practical purposes a closed box wherein in health an equilibrium is maintained between the arterial, venous, and cerebro-spinal fluid pressure; the less of any one of these, the more of the others. When the total pressure exceeds physiological limits there comes a time when the amount of arterial blood is insufficient to supply oxygen to the neurones.

I have dealt with mental disease from the physiogenic side. Are there not, then, psychogenic causes as well? *Certainly there are, and they often yield to psycho-therapeutic measures*, which are, whatever form they take, a deliberate modification on the part of the physician of the patient's higher conditioned reflexes. But their effects are only indirect; the concentrated attention and emotional unrest called worry produce loss of sleep and appetite through endocrine and sympathetic upset, and toxaemia follows. From this stage onwards physiogenic and psychogenic causes march hand-in-hand. I realize that I have given no really practical explanation of mental pathology, but, to tell the truth, we cannot get much further without the intensive work of the biochemist, and the public do not often see the necessity for giving adequate remuneration to a scientific worker who cannot, at a moment's notice, produce rabbits from his hat. The psychiatrist is not wholly to blame for his own ignorance; old legal traditions are powerful, and the state of the law is a heavy drag on our efforts. Nor are our cases easy to manage; they are often restive and always unreliable; they resemble children in that the subjective side of diagnosis is more or less absent, and in many mental conditions even the material obtained for laboratory examination is merely misleading.

HAEMOSTATIC THERAPY IN HAEMOPHILIA

BY

W. W. PAYNE, M.B., B.S.LOND.,

AND

R. E. STEEN, M.D., M.R.C.P.I.

(From the Hospital for Sick Children, Great Ormond Street.)

THE value of most haemostatic drugs can be demonstrated either *in vitro* or by means of an experimental animal. It does not follow, however, that similar good results will follow in the treatment of pathological states. The value of haemostatic drugs in these conditions rests largely on clinical reports based on impressions unsubstantiated by actual measurements. Furthermore, it is highly probable that a drug which might be completely efficacious in dealing with one form of haemorrhage might be quite useless in the case of another. Our conclusions are therefore strictly confined to haemophilia.

In each case the value of the therapeutic agent has been assessed by its effects on the coagulation time. This can be accurately estimated by the Dale-Laidlaw method. Using this method the average normal coagulation time is 1 minute 45 seconds. Values below 1 minute 30 seconds or above 2 minutes are considered to be abnormal. The bleeding time was also taken in each instance, but in haemophilia it is such a variable quantity that it is of little help in diagnosis and quite useless for assessing the value of treatment. It is quite common in haemophilia to find a normal bleeding time.

Inasmuch as the bleeding from a simple needle puncture in a normal subject often stops before clotting can have occurred it follows that other factors besides clot formation must be involved. Two possible mechanisms are: (1) contraction of the capillary walls, and (2) aggregation of platelets sealing the injured wall (Tidy[1]). In haemophilia there is no known damage to the capillary walls and the platelet count is normal. It is not, therefore, surprising that the bleeding time is often normal. The prolonged bleeding times sometimes found are probably due to puncture of larger vessels, in which case the formation of a clot is necessary to supplement the action of the above two factors. The condition in thrombocytopenic purpura is in direct contrast to this. Here the capillaries are easily damaged and the platelet count is low, and so, despite an almost normal coagulation time, the bleeding time is markedly prolonged.

CASE REPORTS AND RESULTS.

Four cases of haemophilia were investigated.

CASE I.—Male, aged 6. No family history of "bleeders" was obtained. Of two brothers, one was normal and the other had a coagulation time of 2 minutes 18 seconds. The subject himself had frequent haematomas and haemorrhages into his joints. The blood platelet count was 243,000 per c.mm. The Wassermann reaction was negative.

CASE II.—Male, aged 2; an only child. There was no family history of bleeding. He has had several effusions, presumably haemorrhagic, into his joints. While in hospital he cut his tongue and bled for six days, losing much blood. The platelet count was 245,000 per c.mm.

CASE III.—Male, aged 9½. Family history of "bleeders" obtained. He had been in hospital twice before, once for a small wound, and once for teeth extraction.

CASE IV.—Male, aged 5. Family history of "bleeders." On two previous occasions he had been admitted for haemorrhages. Once transfusion was necessary before bleeding stopped, and once injection of his mother's serum controlled the haemorrhage (technical data not available). On the present occasion it was necessary to extract a tooth, and, despite all the usual local treatment, haemorrhage could not be controlled.

In all these cases the bleeding time showed marked variation without any relation to either the coagulation time or the therapeutic substance used. Most of the values obtained were normal. The following figures show the range of the bleeding time in each subject:

Case I	30 seconds to 12½ minutes.
Case II	1¼ minutes to 4¼ minutes.
Case III	15 seconds to 4½ minutes.
Case IV	45 seconds to 3¼ minutes.

THE METHOD OF INVESTIGATION.

Most of the substances have been examined in two ways: (*a*) The immediate effect has been studied by determining the coagulation time at frequent intervals after a single dose. The coagulation times were estimated before giving the substance, and then for one hour, at quarter-hour intervals, except occasionally, when estimations were made every half-hour. After the first hour two further estimations were made at about hourly intervals. (*b*) The prolonged effect has been studied by determining the coagulation time before, during, and after a series of doses.

Haemoplastin.

Immediate Effect.—Case i was given 4 c.cm. subcutaneously. The coagulation time fell from 5 minutes 58 seconds to 5 minutes 35 seconds in one hour, and then rose to 6 minutes 49 seconds in two hours.

Prolonged Effect.—Case i was given 2 c.cm. subcutaneously for five days. The coagulation time fell from 5 minutes 8 seconds to 4 minutes 48 seconds on the first day, and rose to 6 minutes 25 seconds on the sixth day. In Cases ii and iii no fall in the coagulation time was observed, but there was a definite rise by the end of the period.

Coagulin Ciba.

Immediate Effect.—Case i was given 20 c.cm. intramuscularly. The only change in the coagulation time was a rise at the end of one hour from 5 minutes 35 seconds to 7 minutes 45 seconds, which lasted for at least two hours.

Prolonged Effect.—Intramuscular injections of 20 c.cm. were given for four days; there was no change in the coagulation time.

Effect of Oral Administration.—Case i was given 1 gram; there was an immediate increase in the coagulation time from 5 minutes 55 seconds to 8 minutes 23 seconds, followed by a rapid decrease to 5 minutes. Within an hour the coagulation time had returned to its initial value.

Fibrogen Merrell (Tissue Fibrinogen).

Immediate Effect.—Subcutaneous injection of 2 c.cm. produced only a small increase in the coagulation time.

Prolonged Effect.—2 c.cm. were given subcutaneously for three days; no change occurred.

Effect of Oral Administration.—On an empty stomach 3 c.cm. in 6 oz. of iced water were given to Cases i, ii, and iii; 6 c.cm. also were given to Case i. In Case i, with 3 c.cm. the coagulation time fell from 5 minutes 30 seconds to 4 minutes 10 seconds in three-quarters of an hour, rising to 7 minutes 37 seconds in one and a quarter hours. With 6 c.cm. the coagulation time fell from 5 minutes 53 seconds to 3 minutes 29 seconds in a quarter of an hour, and rose to 7 minutes 42 seconds in one hour. In Case ii the initial coagulation time was 9 minutes 48 seconds, and during the test it varied irregularly between 8 minutes 32 seconds and 10 minutes 52 seconds. In Case iii the coagulation time rose from 3 minutes 15 seconds to 3 minutes 52 seconds; 6 oz. of iced water alone given to Case i caused the coagulation time to fall from 5 minutes 45 seconds to 4 minutes 17 seconds, with no subsequent rise above the initial time.

Horse Serum.

Immediate Effect.—After 20 c.cm. had been given subcutaneously to Case i there was an initial fall from 5 minutes 44 seconds to 5 minutes 3 seconds, followed by a rise to 6 minutes 23 seconds.

Prolonged Effect.—On two days 10 c.cm. and on the third day 20 c.cm. were given subcutaneously to Case i; no change occurred.

Protein Shock.

(*a*) *Typhoid Vaccine.*—Doses of 10, 20, 50, and 200 million of mixed typhoid, A and B, were given to Case i; no general disturbance occurred and no change in the coagulation time, except after the last dose, when there was a fall from 5 minutes 32 seconds to 4 minutes 3 seconds, within an hour, followed by a rise to 6 minutes 50 seconds after two and a half hours.

(*b*) *Milk.*—Subcutaneous injection of 5 c.cm. of boiled milk caused a fall from 5 minutes 36 seconds to 4 minutes 23 seconds at the end of one hour, followed by an increase to 6 minutes 6 seconds three hours later.

(*c*) *Peptone.*—5 c.cm. of a 5 per cent. solution of Witte's peptone were given subcutaneously. Owing to an error the peptone was given before a coagulation time was obtained. The value ten minutes after was 4 minutes 28 seconds. (The average value for Case i was 5 minutes 30 seconds.) Half an hour later the coagulation time was 5 minutes 24 seconds, and no further variation occurred.

Calcium.

Immediate Effect.—Half a grain of calcium chloride was given to Case i intravenously; the coagulation time increased within twenty minutes from 4 minutes 16 seconds to 8 minutes 2 seconds.

Prolonged Effect.—For three days 7 grains of calcium lactate were given daily to Case i; no change resulted. Case iii was given 5 grains three times a day for seven days; a small decrease in the coagulation time occurred.

Citrated Human Blood.

Transfusions were given to Cases iii and iv; in both the bleeding stopped within a quarter of an hour, and the coagulation time the next day had fallen in Case iii from 13⅔ minutes to 3 minutes 55 seconds, and in Case iv from 11½ minutes to 3 minutes 40 seconds. In Case iii it returned to the initial level in six days; in Case iv, on the third day bleeding started again, although the coagulation time had risen to only 4 minutes 13 seconds, and further treatment was necessary.

Citrated Human Plasma.

Case i was given 25 c.cm. of citrated human plasma intraperitoneally, with no effect. Case iv was given 10 c.cm. of citrated human plasma intramuscularly on the fourth day after the transfusion; the coagulation time was not altered, and the bleeding, which had restarted on the day before, continued. The next day 30 c.cm. of plasma which had been kept five days in the ice-chest were given intravenously, and after an interval of two hours the bleeding ceased and the coagulation time, which had risen to 5 minutes 11 seconds, fell to 3 minutes 6 seconds, and remained at that level for over forty-eight hours. The coagulation time then very slowly rose, but even after two weeks had not quite reached its initial value.

DISCUSSION.

In this study we have kept in mind the following three points: (1) Can any treatment produce a permanent improvement in haemophilia? (2) Can any treatment produce a temporary improvement? (3) What is the best form of pre-operative prophylaxis?

It may be stated at once that no known agent has any permanent effect in haemophilia. Any improvement in the coagulation time which we found was of a temporary nature. As many of the substances used contained animal protein the question of the effect of protein shock on the blood coagulability will be considered first.

It is accepted by most authorities that foreign protein, when injected into the body in sufficient amount to produce some degree of shock, causes a stage of hypercoagulability followed by one of hypocoagulability. There is, however, for every individual an optimal dosage varying with the type of protein used. Too small a dose results in no appreciable change in the coagulation time; too large a dose shortens the period of hypercoagulability and augments that of hypocoagulability until finally the effect on the blood is for all practical purposes merely to increase the coagulation time. According to Pickering,[2] "success depends on the use of a haemostatic of the required activity and upon the subject not being hypersensitive to its reaction. The optimum dosage is one which will produce a 'plasma shock' with minimal excitation of general shock." It will be clear that finding the correct dosage must be to a considerable extent a matter of chance.

In our hands protein shock, by means of typhoid vaccine, peptone, and milk, produced the normal type of response—namely, a transient state of hypercoagulability followed by one of hypocoagulability. In no case was the actual fall in the coagulation time at all impressive. The responses obtained from the other haemostatic drugs administered so resembled protein shock as to raise the question of whether their effect on the coagulation time in haemophilia was due to the small amount of animal protein present in each preparation. In every case the response was either one of hypercoagulability followed by hypocoagulability or one of hypocoagulability alone. On the other hand, this type of response may also be due to a generalized reaction to a substance tending to cause local clotting (cf. Pickering)—as, for example, with calcium chloride. Following its administration the coagulation time rose rapidly, so that within twenty minutes it was nearly double the initial value. There is no question here of protein shock. In either case the question of dosage must be carefully considered, as there appears to be an equal liability for a

period of hypocoagulability to result. While in the case of adults the size of the dose has been fairly definitely laid down, in children the matter is by no means so clear, and in some cases we have possibly erred in not reducing the adult dose sufficiently.

The only form of treatment that was found to be of any real value was intravenous injection of either citrated whole blood or citrated human plasma; citrated plasma given intraperitoneally or intramuscularly was without effect. Citrated human plasma, as pointed out by Feissly,[3] has the advantage of not requiring a preliminary blood grouping, and the use of human plasma prevents any danger of anaphylaxis. Furthermore, both with whole blood and plasma no stage of hypocoagulability occurs. According to Christie and Gulland,[4] fresh intravenous human serum has only a very small effect as compared with whole blood, as shown by coagulation times; in fact, both Feissly and Christie and Gulland find that no substances other than whole blood or plasma have any but the slightest effect on the coagulation time. Emile-Weil[5] states, however, that monthly subcutaneous injections of human or animal serum prevent spontaneous haemorrhages and reduce the coagulation time, but apparently not to the same extent as plasma or whole blood.

SUMMARY.

The bleeding time is of no value in indicating the liability to haemorrhage in haemophilia.

No method except the injection of intravenous whole blood or plasma produced more than a transient unimportant improvement in the coagulation time. In the majority of cases a period of decreased coagulability occurred of longer duration and greater magnitude than the preceding stage (if any) of increased coagulability.

The most effective agents, both for treatment and preoperative prophylaxis, are citrated whole blood and citrated plasma given intravenously.

We are indebted to Dr. R. Frew and Mr. O. L. Addison and Mr. Tyrrell Gray for permission to use their cases, and also to Miss E. M. Taylor for some of the coagulation times.

ON THE ORIGINS AND TREATMENT OF DYSPEPSIA.*

BY

LIONEL JAS. PICTON, M.A., M.B., B.Ch.,

HOLMES CHAPEL, CHESHIRE.

[*Abridged.*]

IT will be well to concentrate upon what I am, perforce, daily familiar with, the natural history of dyspepsia, and upon the lines of treatment that seem justified by the results; for you may try many keys, but the one that will turn in the lock is probably the right key.

Now the data of the natural history of disease are mainly stories of the patients seen. They cannot for the most part be expressed in percentages or graphs. The composite picture, which is in fact our collected experience and our concluded opinion derived from it, can best be drawn by telling the stories of a few patients and making comments upon them as we go along. For brevity, what is printed below consists mainly of the comments.

(A case of acute influenzal dyspepsia, with facial herpes was mentioned.)

Again and again it will be found that, if we dig into the history of a dyspepsia, a common cold was at its root. Or, not uncommonly, as in this child, a transient febrile malaise was associated with gastro-intestinal symptoms. The child was quickly relieved by a few doses of salicin. Since Mr. E. B. Turner taught us all to use salicin in influenza, I have found it of the greatest use, not only in the major epidemics, but also in catarrhs and chills. What I want to bring out here is that it is at least as useful, if not more, in the cases of febrile malaise with digestive symptoms as in those with respiratory symptoms in which, perhaps, it is more commonly employed.

That a facial or labial herpes may accompany acute gastritis was taught by Austin Flint and by Sir William Osler. But I notice that a recent textbook of medicine, encyclopaedic and many-authored, makes no mention of this tell-tale associative sign. It is a sign which, to my mind, clinches the association between acute gastric catarrh and influenza.

(Cases in which gout and trauma played a part were discussed.)

I think trauma was the primary factor in the case I am about to relate.

A man of 30, a yardman at a chemical works, who for several days had been suffering from indigestion attributed to a meal of pork, and from constipation, visited a football match and was crushed in the crowd. He sustained a severe pressure in the upper abdomen. This incident happened at the end of April, 1927. He felt pains in the affected region for a week afterwards. None the less he continued at work. Now the work that fell to his lot from the 1st to the 6th of May was heavy—shovelling heavy clay; moreover, the weather was wet. He was constantly wet through and chilled; and he became very constipated. He felt sick, but could not be sick. A week later he began to have an aggravated indigestion, which culminated, seven days later, in an attack which woke him at 3 a.m. He awoke to find himself lying turned towards his left side and in great pain. The pain was situated in the left hypochondrium. It made such an impression on his mind that he noted the exact time of its awakening him.

After a short while he rifted up wind, and that gave him relief from the worst of the pain. He lay still abed till morning.

Now when one listens to a patient relating such a story as this, it is inevitable that one's mind should follow the imagined stages of the progress of the conditions and changes in the viscera which were related to the symptoms as they emerged into the picture. First there would be trauma, some bruise of stomach or intestines. Then the damaged tissue or a thrombosed vein would be open to infection, or, in the stomach or small gut, to digestion; and an ulcer might result. A. J. Carlson goes so far as to say that the stimulation of any sensory visceral nerves makes the pylorus contract or stops its relaxation; whilst Carnot showed that crushing of various organs, or of the parietal peritoneum, had the same effect.* In this case there were aggravating factors in the next few days which may have mordanted the damage, so to speak, and rendered it permanent—cold and wet, heavy labours—aggravating circumstances these, which, adding catarrh and further causes of stasis to the original trauma, established it as a gross lesion.

Then came the day in which he awoke in agony, lying turned towards his left side. The tension within the stomach will be greater in that position than in any other. And it is undue tension that is the common provoker of pain in a hollow organ. Patients often complain that they cannot sleep on the left side because they can hear a pulse beating. I suppose the weight of the liver pressing upon the full, closed stomach, and increasing the tension in it, has something to do with producing this symptom. Turning on to the opposite side cures it. I suppose that it cures it partly by taking the weight of the liver off the stomach, and partly by allowing gravity to help the exit of the food via the pylorus.

If an ulcer had formed in my patient as the result of the crush, the likely site would be the first part of the duodenum. By the time he came under my care, nearly two years later, such an ulcer might have healed and broken down many times, as we see small varicose ulcers do in the leg. Some such lesion would be the most likely with the history he brought. For this first part, the "duodenal cap" is the most vulnerable length—the "hammock hook" from which the stomach is slung, dragged upon when violence is done to the belly.

Assume, then, that an ulcer had formed in my patient in this vulnerable spot: that would explain the nocturnal

*A paper read before the Oxford Division of the British Medical Association at the Radcliffe Infirmary on March 27th, 1929.

*Even after the vagi were cut in the neck. The splanchnic nerves are the path of this reflex.

attack. The ulcer would provoke the stomach rapidly to empty the first part of the meal last taken.* The duodenal cap and the ulcer would be filled with acid chyme. The mere flood of acid is not enough to cause ulcer pain. There is another factor, otherwise there would be no remission; whereas there is often complete remission. Nor do the contractions of the stomach and gut alone provoke pain; for when they have been watched by radiologists, sweeping over the antrum, and restarting sometimes, or starting afresh sometimes, in the pyloric cap, it has been noted that whilst some synchronize precisely with pains, others are entirely painless. It seems there is a third factor besides the acid flood and the contractions. What is this third factor? The authorities speak vaguely of a sensitizing process. Palmer found the ulcer sensitive to acid on some days and not on others. But when I read, in Alvarez's book, a hint which, he tells, Ivy gave him, I felt we were "getting a little warmer," as the children say.

Ivy's hint was got from some animals in which he had closed one end of a loop of bowel and sewed the other end to an opening in the abdominal wall. The bowel at the mouth of the fistula was quite insensitive. That, of course, is familiar enough. But Ivy's further observation, I think, is of an order hitherto unfamiliar, that when the mucous membrane became everted and swollen, then, if it were pinched, great pain and sometimes vomiting resulted. The fashionable metaphor is that the threshold for stimuli has been lowered. Similar conditions, around the edge of an *ulcer*, account, he suggests, for the continuous pain: and the acid flood may play a part, indirectly, by aggravating the swelling of the mucosa.

After the first rapid rushes through the pylorus which radiologists associate with duodenal ulceration, there is a reversal of the process, a spasm of the sphincter and a hold-up of the stomach contents. The normal regurgitation of alkali from the duodenum into the stomach thus fails, *and the acidity of the stomach contents is accordingly* prolonged. Downward peristalsis in the stomach and reversed peristalsis in the duodenum meet at the closed doors of the pylorus. It was at such a moment, I imagine, that my patient awoke in agony. You will recall the way in which the agony was at last relieved—namely by rifting up wind. The relief, then, came by reversed peristalsis starting in the stomach.

All this happened nearly two years before the man came into my care; but the events he related had ushered in a long period in which the dyspepsia was chronic, the patient despairing of relief. At first he could not work, and was on the sick list for twelve weeks. Then he returned to duty, and managed some work; but his employers, valuing him, gave him that rare and much coveted employ, "a light job."

But he worked in wretchedness. He often felt sick but could not be sick. He was constantly conscious of pains and uneasiness, especially about the left hypochondrium. He had lost his appetite, and had lost weight.

Well, this man got well; or so nearly so that the phrase is justified. And the change followed rapidly on a reorganization of his diet.

Will you allow me to refer to his meals, the changes and reasons for making them, also to his habits?

A remark made by the patient that his bowels were moved daily on getting up in the morning led to a review of the physiological event which precedes a normal action of the bowels, the rush or heave which starts in the colon when food is taken into the stomach. My patient had not taken food into his stomach since the previous night, and therefore I felt there was something wrong. His early morning action was eight or ten hours belated.

Now inhibition is all very well, but it must not be done to death. A patient whom Alvarez mentioned in whom the mere thought of food produced an urgent desire to defaecate was much disadvantaged thereby. His condition was abnormal. But surely the opposite condition also is abnormal, that in which the desire has been so habitually repressed that the sensation passes off and the faeces meanwhile accumulate, not only in the pelvic colon, but in the distended rectum.

In taking that view I find myself opposed to one whose opinion is worthy of very great respect, Dr. Hurst. He thinks that the accumulation which follows several meals may normally be stored in the pelvic colon. The simile of Alvarez is apt. As, when several railway trucks are set rolling down an incline one by one, and come to a standstill when they have exhausted their momentum on the level, though the later ones reach and touch the earlier ones and run together in a group in contact with one another, yet one coming later still, bumping into the group, gives a momentum which is so conveyed through the group to the first wagon of all that that is bumped off the group again and sent rolling independently—*so*, thinks Dr. Alvarez, and *so*, thinks Dr. Hurst, is the accumulation in the pelvic colon normally voided.

That this happens I admit. That it should happen does not seem consistent with full health. As many actions as there are *full* meals seems more normal—for instance, after breakfast and between the last meal and bedtime. Every medical student knows that the two parts of the digestive tract from which the subject derives sensation are the mouth and the rectum; and that it is no more normal for the second to be kept full than the first. Every general practitioner knows that a rectal examination made after a good meal will find the rectum loaded, despite a complete relief "that morning after breakfast." The fact, I think, is that the viscera in question are built to deal with a twelve-hour load, and find it hard to deal with a twenty-four-hour load. The pelvic colon extracts water. The final faeces may be more than twice as concentrated as the fluid that comes through the ileo-caecal sphincter. Two actions daily imply a lower degree of concentration—that is, a softer faecal mass evacuated and a greater *total* weight of faeces. Imagine the difference between a pelvis weighted during the hours of sleep with an accumulation bulging the would-be collapsed rectum, and the pelvi-rectal kink accentuated by a further accumulation in the sigmoid; and, on the other hand, a pelvis from which all the accumulation had been voided at bedtime. To my mind the loaded sigmoid and rectum "keep bad neighbourhood," as our forefathers used to say, with the adjacent organs—with for instance, the uterus in the pre-menstrual epoch: or with the prostate. I dare to think that a morning and an evening action, habitually and naturally obtained, may be reasonably thought of as in some degree prophylactic against enlargement of the prostate.

The relief of headache and sense of pressure in the head following a timely evacuation of the bowels is too prompt to be due to the mere removal of bad chemical influences. It must be due to an adjustment of what Mr. Hilton called the equipoise between the cerebro-spinal fluid and the venous circulation. The relation between the pressure in the cerebral ventricles, the gastro-colic reflex, and defaecation was familiar enough to John Arderne in the fourteenth century: "And witte thou, . . . that the synowez closyng and openyng the lure [rectum] hathe festnyng with the stomake and with the ventriculez of the brayne, And for this cause suche pacientez ar som tyme vexed in the heued and in the stomak."

He is right, too, about those "vexed in the stomak." The increased commonness of appendicitis is no doubt due to the increased commonness of a single daily action. But I would go a little further and say that a great part of the dyspepsia from which sedentary people in middle life commonly suffer is the "expression" of reverse peristalsis quietly rippling back every now and then along the ileum, jejunum, and duodenum as a reflex from a stuffed rectum and *loaded colon*.

Meat and starchy foods were to be taken at separate meals. Pavlov showed how the mixture of meat and starch was delayed in the stomach twice as long as meat alone. The reason why bread was (in the diet prescribed) withheld as often as possible is empirical. The explanation of the observed benefit may be that bread is a sponge and that the starch in it is therefore difficult of digestive attack. In any case, as the starch grains are unburst they have to wait till they reach the duodenum for digestion.

Dinner was soup, meat and greens, and fruit. The greens were to be ample in amount, to be boiled five minutes* by the clock, to be shaken free from water but

* Galen knew this. "The stomach, when, as often happens, it is irritated by acidity, gets rid of the food, although still undigested, easier than proper." (Galen: "On the Natural Faculties." *Loeb*. III, v.)

* Plunge them in boiling water. Count the five minutes from the time you hear the water come back to the boil.

on no account squeezed, and to be dressed plentifully with butter. No one who has not had green vegetables thus prepared can realize that they can be so much more acceptable than when they are cooked twenty minutes or half an hour in the ordinary way. Ninety per cent. of people who really try this method remain firmly attached to it.

The plentiful dressing of butter or dripping with the greens is of importance, and the oil to be used with salads —*for three reasons:*

1. A natural alliance between vitamin A and fat.
2. The calorie value of this diet, lowered by reduction of starch, is raised by the fat.
3. Fat, passing the sphincter of Oddi, stimulates contraction of the gall-bladder.

Suppose a stomach reasonably filled, after soup (which soon runs out) with a little grilled meat, with greens or salads, yielding, as they do, 3 per cent. of their 5 per cent. of starch, and with fruit, digestion is facilitated. Equally filled with food rich in starchy carbohydrates, such as the conventional bread, potato, and rice pudding which form the bulk of the so-called meat meal of the middle and working classes, the stomach would often be overtaxed with foods of a texture it was not constructed to handle, and which would be delayed in transit by the presence amongst it of meat.

From a mere calorie point of view unnecessary carbohydrate must often be taken at such meals merely to provide the bulk required to still and tranquillize the stomach—bulk which could be better provided by green leaves or by fruit, foods of a more suitable texture and without excess of nourishment.

So much for the principles of the diet which brought relief to the patient instanced, the yard-man at the chemical works.

(Instances of dyspepsia excited by influenza, colds, catarrhs, gout, trauma, and excessive and unsuitable food were reviewed.)

Not a few large eaters eat too much of too concentrated food because constipation gives them an instinct to take in such a bulk of ingesta as will restart the gastro-colic reflex and steepen the gradient. Dr. Drysdale (of St. Bartholomew's Hospital) once advised me to give such patients boiled cabbage stalks.

Constipation is a feature of most cases of dyspepsia. The "gradient" is "flattened," Alvarez would say, and requires to be "steepened." Curiously enough, he seems much more anxious about devising "smooth diets," and eliminating cellulose, and in dealing with the reflex irritation of colitis than in restoring what Hippocrates would call the stronger diet of pristine health.

(But that this latter policy can succeed, another case with emaciation and constant vomiting was related as evidence. Finally a patient with gastro-jejunal ulcer, who declined further operation, was described.)

I have tried to tell my very ordinary stories and thereon make my comments, which constitute a mere mental flotsam and jetsam washed up upon the beach of an average medical experience. But I should like to gather a few specimens from this flotsam and jetsam which will have at any rate this merit, that they will be debatable.

Here is the first:

A diet mainly of grilled meat including liver, and fish including roes, and green leaves including lettuce and cabbage, and fruit will often cure a chronic dyspepsia. Perhaps such food as that succeeds because it must be closely similar to the food of primitive man. Anthropoid apes live on leaves, young green shoots, some roots and barks, some meat—for example, the baboons in the Zoo are known to catch and eat grey squirrels and birds. Such food is, in essentials, not far removed from the meat, greens, and fruit diet I have spoken of.

Dr. Chalmers Mitchell says people kill their tame monkeys with cereals. The misuse of cereals causes an incalculable amount of disease and death amongst mankind.

The production and use of cereals has, according to Sir Arthur Keith, made civilization possible. With the change of habits that came when the hunter became the husbandman there came no corresponding change in anatomy. The human digestive tract is still that of man the hunter. In youth and health it (the human digestive tract) is elastic and adaptable enough to manage with a very wide range of kinds of food. But just as presbyopia comes with age so does less adaptability in the matter of food. Many dyspepsias of middle life are due to persisting in the diet that did well enough in youth. More or less of a return to or towards the meat-fish-greens-fruit diet is indicated.

Starchy food must be surrendered judiciously; and hydromel—that is to say, honey and water—an eggcupful at a time, is occasionally useful as a drink for odd moments in persons who give up a good deal of starchy food but feel weak without it. (I understand the levulose in the honey requires very little labour at the hands of the liver.)

The starchy food that is best tolerated is porridge at breakfast. The porridge should be made in the old Scottish way, scattering the meal into *boiling* water and stirring the while. The importance of this detail is that the aleurin envelopes of the starch granules should be burst so that the starch becomes mucilage. Ptyalin is said not to digest starch unless it is boiled. It is hard to accept this limitation. What was the ptyalin for, before men learned to cook?

Dyspeptics should not eat starchy food and meat at the same meal. (See reference above to Pavlov.) From that embargo surprising consequences flow—for example, a sandwich of meat and bread is an example of forbidden food, so is a pork pie, so is a plate of meat and potatoes so is fish and bread-and-butter, so is a sausage, which is a mixture of meat and bread. On the other hand, a sandwich of cold boiled bacon (which is practically fat) and brown bread is permissible. This is important in working class practice where dinner has to be carried out.

A useful formula for middle-class people is "fish one day liver two, meat the rest, but chicken on saints' days." (The last phrase is not intended literally.) The potato dinner may be substituted for one of the meat days.

Amylaceous dyspepsia used to be thought to be associated with fermentation of starch delayed in the stomach and consequent gas production. This, so stated, is now known to be seldom true (apart from pyloric obstruction. Amylaceous dyspepsia is associated with constipation.

Since 1872 the stone mill has gradually been replaced by the steel roller mill. The rise in the sale of patent aperients has gone up concurrently. Wholemeal flour will not keep, because the germ contains a ferment. Attempts to stabilize it, by treating the germ with superheated steam, succeed, at the expense of destroying the thermolabile moiety of the vitamin B. It is better to use wheat freshly ground. I don't know whether the vitamin B has more to do with preventing constipation than cellulose. The diet which keeps Eskimos in health contains no cellulose, but the vitamins are there got second-hand through the organs and fat of the animals and fish eaten. I suppose they, in their turn, get them from small creatures—crustacea, myriad copepods—and those get them from the vegetable *plankton*, algae and diatoms. So the Eskimo gets them really fourth- or fifth-hand, not second-hand. The substitution of manufactured food, imported into Labrador, for the traditional diet, which was similar to that of Eskimos, has, I understand, been followed by illness and physical degeneration.

The commonest sort of dyspepsia is due to constipation producing reversed peristalsis in the jejunum and duodenum, and in the ileum too. The greatest pain probably happens an hour or so after meals, when the pylorus closes against this reverse peristalsis. The gentle reversed peristalsis which may in healthy digestion wash a little alkali chyme back into the stomach at about the same interval after a meal, finds the pylorus a compliant janitor. But to the backward surge of the dyspeptic he is at first adamant. Constipation enough to call forth these effects may be present in spite of a daily action. To eat when cold feet seems to invite an aggravation of the reverse peristalsis.

The condition of amylaceous dyspepsia *plus* constipation must result in different intestinal bacteria predominating from those which predominate in full health when

rectum is emptied fairly soon after it is filled. Comparative studies of the ecology of the constipated and normal intestine would, I think, reveal a very different flora.

The "climax association" (as I think the ecologists call the most permanent partnerships of living things*) in severe types of chronic constipation may show a haemolytic streptococcus dominant and thus explain the anaemia. Other bacteria in the small gut may be engaged in fermentation of kinds which do not go on in health. To that extent there still may be truth in the old idea that amylaceous dyspepsia may be due to fermentation, even though the stomach itself be exonerated.

To reverse the diet from the civilized prepared cereal food to the polite equivalent of an uncivilized diet is a great means of health to such people. But they cannot wait, and medicines may give quicker relief. The best I have found is iodine and cajuput:

℞ Tr. iodi		nx
Ol. cajuputi		mij
Mucilag.		q.s.
Aquam	ad	3j

Sig.: t.d.s.; 10′ a.c.

Its action seems best explicable on the theory that some of the symptoms are produced by fermentation. A laxative will be required for a time, such as the popular emulsion of paraffin with agar and phenolphthalein, but only for a time.

CAVERNOUS SINUS THROMBOSIS WITH RECOVERY.†

BY

E. A. SEALE, M.A., M.D., B.Ch.,

OPHTHALMIC SURGEON, SETTLER'S HOSPITAL, GRAHAMSTOWN, SOUTH AFRICA.

CAVERNOUS sinus thrombosis is comparatively rare and all authorities describe it as a fatal condition. Parsons[1] says "the patient always dies." McCallan,[2] opening the discussion at the Ophthalmological Society of the United Kingdom last year on the diagnosis and treatment of inflammatory affections of the orbit, refers to it as "this fatal affection." The most favourable views I have found are Posey's,[3] "barely 7 per cent. of cases recover," and Collins and Mayou's,[4] "if the clot be septic death usually follows, but in aseptic cases the patient may live; the exophthalmos continues, optic neuritis with atrophy following."

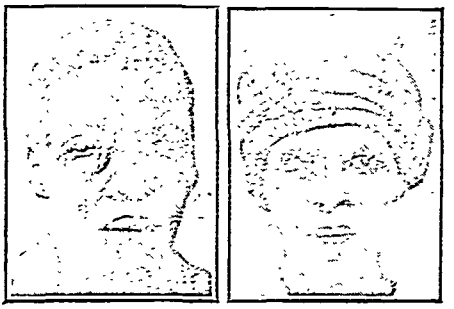
Most authorities, I believe, base their conclusions on their study of the condition in European patients. The wonderful powers some South African natives have of resisting certain infections may account for the survival of the patient whose case is now to be described.

A Kafir woman, aged 30, the mother of seven healthy children, was sent to me by Dr. Ella Britten on August 18th, 1922. She was thin, weak, and flabby, with quick pulse, and had her year-old baby with her—still at the breast.

The history she gave me—and I must emphasize the vagueness of the native where exact dates and figures are concerned—was that her eyes were perfectly well until shortly after this last baby's birth. The confinement had been severe, and recovery long delayed. Pain began in the left eye with headaches; the eye got red and very large, and pain was also felt behind the left ear. Dr. Britten saw her when this left eye was proptosed—a most valuable observation as regards subsequent diagnosis. The patient says this condition lasted some months, and then the right eye went through changes similar to those of the left, while the latter decreased in size. Eye pain and headaches were also similar.

On the date of her first visit the right eye was proptosed directly forwards to the extent of three-quarters of an inch. Chemosis was so marked as entirely to conceal the lower lid. Conjunctival congestion was trifling and limited to the upper part of the bulb. The ciliary vessels showed no fullness. The cornea was exposed fully, but three-quarters of its surface could be covered on effort. It was hazy and oedematous but still bluntly sensitive, and gave a mottled staining with fluorescein. The pupil was semi-dilated and insensitive to light. Tension was soft—17 mm. Schiötz. The eyeball was fixed and could not be moved by effort. The media were clear, allowing for corneal haze. The disc was somewhat pale. The field of vision was diminished between the macula and nerve-head. Right vision: 6/36; c. + 2.00 sph. = 6/24. Left vision: able to count fingers at 6 feet.

The left eye seemed fairly normal, though deviating upward and outward. No inward movement was possible beyond the midline, and fixation was difficult and transient. The pupil was



enlarged and very sluggish even to strong light. The media were clear. The disc was pale on the temporal side; its edges were sharp, and its vessels were not enlarged. The tension was normal. No bruit was complained of or listened for over the frontal region. She was ordered a simple boric lotion, the cornea being protected by a pad and bandage over boric ointment.

On August 28th the proptosis was less. The cornea was clearer and could be entirely covered by the upper lid. A photograph was taken.

On September 4th there was slight movement up and down of the right eye. The conjunctival chemosis was pricked and sanious fluid let out, which considerably lessened the proptosis.

On September 9th the condition was as before; the conjunctiva was again pricked with good result. On this date the patient was shown at a British Medical Association meeting and agreement was expressed with the diagnosis.

Five days later she began taking a mixture containing potassium iodide in moderate doses, and at her next visit, on September 20th, she looked and felt better. The proptosis now allowed a finger-tip insertion between the bulb and bony orbit above. Movement was increased in all directions. Her visual acuity remained unchanged. The potassium iodide in the mixture was reduced to 2½ grains in each dose, as signs of iodism were present.

I did not see her again till the following January. Though the eye had changed little in appearance, vision was now reduced to counting fingers at two feet. The field of vision also was much lessened. The cornea was dull and hazy, and it was impossible to make a detailed examination of the fundus. She said she felt stronger and better, but still complained of occasional pain in the eye region and the vertex.

It was four years later when I next saw her—February 4th, 1927. The right eye was now quite shrunken into the orbit, and, of course, absolutely blind. The left eye seemed just as at her first visit, both in appearance and acuity of vision. The field of vision was absent on the temporal side right up to fixation point. The disc was as before, but a speckled pigment area was seen impinging on its temporal edge.

In March of this year (1929) she came again. The general health had improved but the condition of the eyes remained unaltered. A photograph taken on this date (March 7th) shows a somewhat healthier and happier-looking woman. I may add that she now earns a little as a blanchisseuse.

However fortunate one may deem oneself in having seen any stage of this case, one must regret the absence of such opportunity in its early stages and before it was seen by Dr. Britten. The definite fact remains that the trouble began in one eye and then appeared in the other. This ensuing bilaterality, which occurs in most cases, has been insisted upon by authorities as a characteristic in distinguishing cavernous sinus thrombosis from orbital cellulitis—the affection most likely to simulate it. A simultaneous cavernous sinus thrombosis of both sides is well known in certain cases of sphenoidal air sinus disease, the close proximity of these sinuses to the cavernous sinus affording an explanation. Immobility was no doubt due in part to paralysis of the ocular nerves, as they lie embedded in the cavernous sinus wall, and in part to venous congestion—all ophthalmic veins emptying into the cavernous sinus.

* For example, heather, Scots pines, and cross-bills.

† Read before a meeting of the Medical Association of South Africa (B.M.A.), April, 1929.

It is interesting to note the low tension of the right eye and to compare it with Foster Moore's[5] observations on intraocular tension in cases of thrombosis of the retinal veins. He states that "in most cases of thrombosis of the central retinal vein the intraocular tension of the affected eye is appreciably less than that of the unaffected eye."

In speculating on the cause in the above case, one is handicapped by the late date at which medical advice was sought. Of the three usually assigned causes—infective, primary or marasmic, and traumatic—I think the first the most likely. It is suggested by the severity of the confinement, prolonged convalescence, and the absence of a history of any head, face, or ear lesion. Statistics also show that the great majority of cases of cavernous sinus thrombosis are of infective origin.[6 7]

PREVALENCE OF ENCEPHALITIS EPIDEMICA IN CHINA.

A CONTRIBUTION TO THE HISTORY OF THE DISEASE IN THE FAR EAST.

BY

MAXIMILIAN O. PFISTER, M.D., M.R.C.S., L.R.C.P.,

NEUROLOGIST, HONG-KONG, FORMERLY ACTING HEAD OF THE DEPARTMENT OF NEUROLOGY, PEKING UNION MEDICAL COLLEGE.

CRUCHET's latest contribution to the literature of encephalitis epidemica has aroused increased interest in the question of the origin of this disease, and since recently a writer published an article suggesting the possible introduction of encephalitis from China, it seems desirable that the data with regard to the history of the disease in that country should be carefully examined and more valuable material collected. I hope the following observations will serve this purpose.

When, in 1921, I returned to China I found encephalitis rather flourishing, and since that time I have observed cases everywhere in the northern, Yangtse, and southern provinces where I looked out for the disease. Encephalitis is nowadays not rare in China, although there are many medical practitioners, even in the large cities of the coastal districts, who have never seen or recognized a case as such. The fact that many medical men in China are still unfamiliar with the picture of encephalitis in my opinion accounts for the paucity of knowledge and documentary evidence of the disease in that country.

The first publication on the appearance of epidemic encephalitis in China was written by W. W. Cadbury,[1] who observed one case in Canton as early as August, 1919. In 1920 Judson[2] described two cases from Anhwei province, and Lennox[3] another case which he had seen in Peking. Later, in the winter of 1921–22, two cases were reported by Wassell[6]—one from a hospital in Wuchang and another from Changsha in Hunnan. With the opening, in 1921, of a special neurological department of the Peking Union Medical College the opportunity for seeing a large number of neurological cases was given, and thus A. H. Woods was able to report on twenty-one cases which he had seen within the first year of the new institution's existence.

During my activities as neurologist at the Peking Union Medical College I made a special study of encephalitis, and the following report comprises my observations on a hundred cases seen during the period of two and a half years (1923–25). The following are the places from which the cases came:

Peking	... 53	Shanghai ...	... 5
Peking (country)	... 13	Mukden ...	... 2
Tientsin... ...	... 7	Chefoo ...	... 2
Peitaiho ...	... 4	Tsingtao ...	... 1
Foochow ...	... 4	Kalgan ...	... 1
Shansi	... 3	Chengtu ...	... 1
Paoting... ...	... 3		
Nanking ...	... 3		100

As the list shows, more than half of the patients came from Peking or its immediate neighbourhood, most of the others from places situated at the coast or near the lines of railway traffic. Szechuan was the furthest interior province from which a patient was sent to us.

The earliest of our cases was a student who gave a reliable account of his disease, the onset of which he dated back to the beginning of the year 1919. For its historical interest the case might briefly be described here.

The patient, aged 25, states that when he was in Shanghai in March, 1919, he had fever for ten days, with dizziness and double vision, followed by sleepiness, which continued for several weeks. Since 1922 he has suffered from difficulty of speech, increased salivation, and involuntary movements of the head and hands. Clinical examination elicited the following signs: typical Parkinsonian posture and gait; myoclonus of the left sterno-mastoid muscle; tremor of both hands; dilated pupils, absence of reaction to light, and paresis of the rectus internus muscles; exaggerated tendon reflexes; negative Wassermann reaction.

Four other patients were admitted who had contracted the disease in the same year, one in July in Foochow, the rest in the autumn in Peking, Paoting, and Tai Yuan (Shansi). The number of admissions of encephalitic cases gradually increased from year to year, probably partly owing to the growing interest of the medical men who had sent these patients to us for further study. There were, in addition, small epidemics in Peking and its neighbourhood, such as in Peitaiho, a health resort at the seaside, where for several years regular outbreaks occurred during the hot summer months. The first cases at the latter place, of which I examined one myself in 1921, displayed rather fulminating symptoms. Four patients died in quick succession; in later years the character of the disease became much milder.

With regard to the season, the frequency curve shows that new cases appeared the whole year round, but, as also happened in other countries, a marked rise was noted, especially in 1923 and the following year, during the winter months December to March, which in northern China form the cold, dry season with dusty winds—the season of catarrhs of the respiratory tract. A second but slighter elevation of the curve set in with the beginning of the dry season in August. On this occasion it is interesting to compare the great outbreak of a special form of encephalitis in Japan in 1924, which occurred in a remarkably dry summer and abated with the onset of the wet season. Most of the patients were between puberty and middle age; the youngest was 5 months, the oldest 61 years of age. Among the 100 cases there were only 20 females; 82 were Chinese, the rest foreigners. Farmers were less affected than people leading a sedentary life; the highest incidence was among the students, with 27 cases; soldiers, who furnished the richest material in neuro-syphilis, were represented only by a single case.

The clinical picture of epidemic encephalitis is essentially the same as in Western countries, and the Parkinsonian type, which occurs in 35 per cent. of all cases, represents the largest group. The earliest appearance of Parkinsonian manifestations was noticed three months after an acute onset with fever, oculomotor symptoms, and lethargy. In most other cases about two years, or even a longer time, had elapsed between the initial symptoms and the first kinetic disturbances. Marked sleepiness was one of the most constant features in the history of this group. In some, especially in young patients, the akinesia reached a very high degree. Neglected by their family, emaciated to the bones, and motionless like a statue, these unfortunates would easily impress the people as beings possessed by some kind of evil demon.

The greasy appearance of the face, a characteristic sign in European patients, has not the same striking significance in patients of the yellow race, since in the latter the skin has already a somewhat shiny appearance. In most cases the oculomotor nerve was involved, with partial paralysis of one or several muscles. In 5 cases ocular crises were observed, with temporary tonic fixation of the eyeballs in an upward direction. Twenty cases belonged to the purely hyperkinetic type, displaying all grades, from the most minute tremor of the lips or hands to coarse choreiform movements of one or several extremities; in the worst cases the whole body was shaken with an intensive general tremor.

Of acute cases, beginning with fever, headache, joint pains, and sleepiness, 25 patients were admitted, of whom 3 with very grave symptoms died a few days after the onset. In one case a post-mortem examination was performed, and the microscopic findings showed an extensive perivascular as well as intrathecal cell infiltration, and degeneration of ganglion cells, most marked in the substantiae nigrae of either side and in the area of the oculomotor nucleus.

As a separate group I should like to consider 15 cases of bulbar forms. They had the character of a small epidemic of a benign nature, and were observed during the winter of 1924 in Peking. Besides ptosis and diplopia, bulbar symptoms were the most prominent features, with difficulty in speech and swallowing and paresis of the accessory nerve. Several of these patients had suffered from a previous catarrh of the upper air passages, and in 5 cases of a striking similarity the possibility of a direct contact infection in the hospital cannot be entirely excluded.

In the same winter a number of cases were seen, monosymptomatic forms with some kind of oculomotor disturbance or more or less marked lethargy, which in my opinion must be classified among the abortive forms of encephalitis epidemica.

The question of the routes by which the encephalitis found its way into China is interesting. Three main possibilities have to be considered.

First, the invasion could have taken place from the east, from America by way of the Pacific and Japan. In its course westward from Central Europe the steps can be traced by which encephalitis gradually reached first the east of England, then its western side, during the spring of 1918, and the east coast of America at the end of 1918. But in the western parts of America the disease was not noticed until the autumn of 1919. Thus, since in China a case had already occurred in March, 1919, it does not seem likely that the infection came the long way over sea from America.

The second route by which the disease could have been introduced is by way of Siberia. In Russia encephalitis had been observed some time before 1919, but in its eastern parts apparently not before the end of that year. At that time the trans-Siberian railway line was still interrupted at various places, and there was as yet no through traffic to China by this route. From investigations I learned that the first cases appeared in Harbin and Mukden at a date later than the autumn of 1919, when the first case was observed in Peking. It seems to me much more probable that the cases in Peking originated in infections from the south along the railway line from Shanghai.

The third possible way is by the most frequented route of sea traffic from Europe by way of India to the ports of China. This appears to be the most probable path by which the encephalitis travelled, for the disease made its first appearance in the southern ports of China, following a course similar to that of other epidemics entering China from the west.

There is another fact which speaks for the great probability of the introduction by the southern route. In the same year that the first cases were known to have appeared in China a small outbreak of encephalitis had been observed in the military barracks in Karachi, and in July, 1919, on the Andaman Islands, which are situated about midway between India and China. Thus it seems quite possible that soldiers were the carriers of the disease to the Far East. I may mention here that in Japan the disease appeared approximately at the same time as in China, probably introduced along the same lines of transmission.

There remains another possibility, explored by Dr. A. J. Watson in a paper entitled "The origin of encephalitis lethargica," which was published in the *China Medical Journal* for June, 1928, and subjected to some criticism in a leading article in the *British Medical Journal* of August 18th of that year. Watson claims to have seen a case of encephalitis in Yunnanfu in 1927, the onset of which, according to the statements of the patient and his friends, was dated back twelve years—that is, to 1915. The case was seen only once in the out-patients' department, and was not thoroughly studied, as Dr. Watson's assistant, Dr. H. P. Yew, admitted in a note in the *China Medical Journal* for January, 1929. A second case seen in 1927 with an eight years' history would have started in 1919, in the same year in which, as we have seen, encephalitis had already made its appearance in other parts of the south and east of China. The rest of Watson's cases are of a still later date. Thus his theory of the origin of the disease in Yunnan practically rests only upon the poor evidence of one inadequately investigated—which is hardly enough to serve as a basis for a new theory.

But even if we could accept this "early" case as proven, we need not assume that the disease really originated in Yunnan. I can offer another much more probable explanation. From my personal experience and further inquiries I am able to state that soldiers from Indo-China were engaged in the battle zone of Verdun, where the first cases were reported to have appeared in 1915, and that in the same year Annamite troops from this front returned to their homes. The railway connecting the coast with Yunnanfu was already in existence, and the infection could thus have been carried within a short time into the heart of Yunnan province. Remoteness and isolation—factors which Watson further mentions in support of the endemic nature of encephalitis in Yunnan—are only relative conceptions; even the poorest traffic would suffice to convey the virus of an epidemic disease by one or the other means.

In 1926 I expressed the view that encephalitis lethargica was introduced into China from the southern ports; I consider it probable that another way in which the disease may have entered China was through the native soldiers of Indo-China. If the disease had originated in Yunnan and thence spread to other parts of the world, especially to the west, we would have seen quite a different epidemiological picture.

SUMMARY.

Encephalitis epidemica is known to have appeared in China early in 1919 and to have spread along the lines of frequent traffic.

In its clinical aspect the disease does not differ essentially from its behaviour in Western countries. The Parkinsonian symptom-complex is the most common sequel.

The epidemic character has been less obvious in China than in Europe, but a few small epidemics have been observed in the north of the country.

There is no evidence that encephalitis has its origin in one of the provinces of China, but enough satisfactory evidence exists to support the assumption that the disease was introduced through Indo-China, and through the ports of the southern and eastern coast of China by means of the sea traffic from Europe through the Indian Ocean.

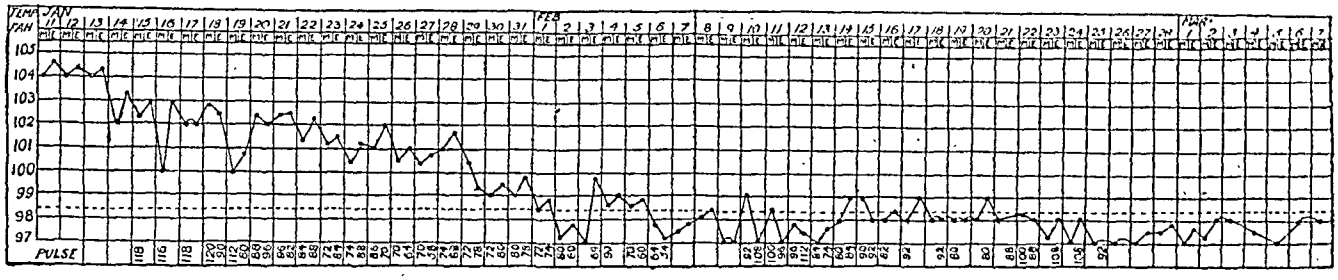
CEREBRAL ABSCESS FOLLOWING ACUTE TONSILLITIS.

BY

E. GERARD HOUSDEN, M.B., B.S.LOND.

THE sequence indicated in the above title is sufficiently rare to make the following case worth recording. No reference could be found in the literature of the subject to a case of cerebral abscess secondary to throat conditions, although foci of sepsis in the lungs, cardiac valves, liver, and bones are mentioned as possible causes. Other remarkable features of this case were the patient's apparent complete recovery after an illness of six weeks' duration, in which he had for a period of a month shown unmistakable signs of an intracranial abscess, and then his comparatively sudden death.

A plumber, a healthy, well-built lad of 18, with no history of previous illness or ear trouble, was first seen on January 11th.



He had been out-of-sorts for several days, and complained of a sore throat. His temperature was 104° F., pulse 120, and respiration normal. The fauces on both sides were intensely injected, together with the posterior pharyngeal wall, which was covered with a muco-purulent exudate. No other physical abnormality could be found. His temperature remained as high for several days, with slight variations in the throat condition, and a good deal of general disturbance. On January 14th the temperature fell to 102°, and remained at this level for the following week, with a relatively slow pulse below 100. On the same day he commenced to have rigors once or twice daily until January 17th, when the tonsillitis began to localize as a peritonsilar swelling on the left side. On January 19th ptosis of the left eyelid and a left internal strabismus were noticed, associated with periods of "sleepiness," although the patient was quite rational when roused. He had some headache, aggravated by attacks of coughing coming on at hourly intervals, in which he expectorated a muco-purulent sputum. On January 18th he was given 1 c.cm. of "S.U.P." intramuscularly, and on January 20th a second injection of this and 25 c.cm. of polyvalent antistreptococcal serum, without obvious effect.

On January 21st he was seen in consultation with Dr. C. E. Lakin, who found rigidity of neck muscles, modified Kernig's sign, left knee-jerk absent, right just present, plantar reflex flexor, ptosis of left eyelid, internal strabismus of left eye, with much congestion of the retinal vessels on this side. The throat still showed some peritonsillar swelling on the left side, but Dr. Lakin detected no abnormality in the chest or abdomen, and suggested the presence either of a cerebral abscess or a basal meningitis. Removal to hospital was advised, but consent was refused.

During the following week the nervous symptoms varied. The ptosis became less noticeable, although the strabismus remained throughout. The neck rigidity continued, with a doubtful Kernig's sign. On January 23rd and 24th all reflexes, except the superficial abdominal, could be obtained. At times the patient seemed sleepy, but he was bright mentally, and his fever continued in the region of 101°, and his pulse rate from 60 to 90 per minute.

On January 25th scattered dry rhonci were found on both sides of the chest, with moist crepitations at both bases, associated with a purulent sputum which, on examination, was found to contain pneumococci, *B. influenzae*, and staphylococci. The cough, which still only occurred infrequently, continued for several weeks, and then entirely ceased.

Nothing further of note happened until the morning of February 2nd, when at 6 o'clock, following an hour's incoherent speech, the patient commenced to have fits. They began by a deviation of the head and eyes to the right, with marked lateral nystagmus and hippus of both eyes. Then followed a clonic convulsion, originating in the right side of the face and spreading to the neck and jaw muscles. Between 6 and 9 a.m. fifteen occurred, and in the more severe ones the convulsion spread to the right and left arms and involved the entire musculature. The knee-jerks remained present, and an ankle clonus was obtained on the right side. No further fits took place, and the next day he was conscious, but at times was "muddled" in his speech. On February 4th he was very delirious, but by February 8th he was comatose, and rolled his head continually from side to side. The temperature was now subnormal, and the pulse rate varied from 54 to 90 per minute. He had become very emaciated.

He was still unconscious on February 9th, when he was seen with me by Dr. D. G. Leys. He found a bilateral ankle clonus, but could obtain no reliable evidence from the reflexes to point to a unilateral cerebral lesion, nor any definite optic neuritis in either eye, but suggested that exploration of the brain was worth considering after further investigation in hospital. Unfortunately no permission for the patient's removal to hospital could be obtained.

From February 10th to 16th the patient remained in a semi-comatose condition, and nutrition was only kept up by rectal feeds of 5 per cent. glucose. Death seemed the only possible issue, but on February 16th he regained consciousness, began to take nourishment, and by February 18th seemed quite normal mentally, although a little excited. The following day an abscess, which had gradually formed on the back, at the site of the serum injection, was opened, and a greenish-yellow pus was evacuated. By February 25th he seemed well in every way, was eating solid food, sleeping well, putting on weight, and normal mentally; he was allowed up for half an hour, with daily increments.

It looked as if our interpretation of his cerebral symptoms had been at fault, and that the abscess on his back had acted as a fixation abscess and brought about a cure, for his improvement was uninterrupted until March 11th. During the morning of this day he was getting about the house, but at midday he seemed sleepy, and at 4 p.m. he became unconscious, and remained so until his end was brought about at 6.30 the next morning, by what was clinically an acute oedema of the lungs.

A post-mortem examination, confined to the brain, performed with the help of Dr. Allen Piggot, revealed an abscess about the size of a walnut in the tip of the left temporo-sphenoidal lobe, with some adhesions between the surrounding pia mater and dura. There was no sign of bone infection in the skull.

It may be pointed out that the cerebral symptoms had already appeared before any abnormality could be detected in the lungs, so that it is probable the cerebral abscess was a direct complication of the acute tonsillitis.

Any incompleteness in these notes is due to the fact that they were gathered in general practice, and that, owing to the refusal of the patient's parents to agree to his removal to hospital, the clinical observations and partial post-mortem examination had to be carried out in a small artisan dwelling.

My thanks are due to Drs. C. E. Lakin, D. G. Leys, and Allen Piggot for permission to associate their names with this case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF PHYSOPYOMETRA WITH PERITONITIC ABSCESS.

MOST of the reported cases of physometra (gas in the uterine cavity) have been associated with septic abortions or other complications of the puerperium. In such cases the symptoms are usually very grave and the issue fatal. The organisms concerned are frequently *B. welchii*, anaerobic streptococci, and *B. coli*. Chronic pyometra is a condition more common, and occurs where retained uterine secretions have become infected, as in senile and tuberculous endometritis, malignant disease of the body or cervix, and suppurating fibromyomata.

History of Case.

The patient, a woman aged 65, was admitted, on January 6th of this year, complaining of offensive vaginal discharge and haemorrhage. She was married, and had two children, aged respectively 29 and 24. She had ten or twelve miscarriages before the birth of her first child.

Fibromyoma uteri was diagnosed thirty years ago, but no treatment had been received. The menopause occurred twenty-three years ago. Three years ago she had slight vaginal haemorrhage, and several floodings had occurred during the last two years. *A greenish offensive vaginal discharge had been present for the last* three months.

She was admitted with an abdominal tumour, arising out of the pelvis to the level of the umbilicus. There was a copious purulent vaginal discharge. Temperature 100° F., pulse 98.

Total hysterectomy was performed by Mr. Victor Bonney. Both tubes and ovaries were removed. There was a small localized peritonitic abscess in the neighbourhood of the fimbriated extremity of the right tube. The appendix was not in the immediate vicinity, did not appear to be involved, and was left *in situ*. The patient made an uninterrupted recovery.

The uterus contained multiple fibroids of varying sizes. Some were cystic and some calcareous. The uterine cavity was distended and fluctuating. On opening the cavity a considerable quantity of gas escaped with a hiss, followed by 1½ pints of greenish-yellow pus with a *B. coli odour*. A soft, friable, fungating mass involved the endometrium and uterine wall in the region of the fundus. Sections from this area showed an adeno-carcinoma corporis uteri. The remainder of the wall of the cavity was lined by a rough pyogenic membrane. Both tubes contained pus. The lumen of the extremity of the left tube was occluded, and it was distended.

My thanks are due to Mr. Victor Bonney for permission to publish the notes of this case.

FRANCIS J. HECTOR, M.D.,
Senior House-Surgeon, Chelsea Hospital for Women.

RAT-BITE FEVER FROM THE BITE OF A PIG.

THE following case is of so unusual a nature that it seems worthy of recording.

On March 20th a woman, in feeding a small pig with a bottle, was bitten on the forefinger; the wound bled slightly and healed normally. On April 4th it began to swell, and continued to swell and become increasingly painful for four days, on the last of which I saw it for the first time. The terminal phalanx was extremely swollen and tender, and I proposed to incise it, but for domestic reasons she wished it postponed to the next day. On April 8th it was excised freely under gas; no pus was found and there was very little bleeding at the time; it bled normally later and the pain was relieved considerably. Boric fomentations were applied, but there was no discharge, and the next day the wound was almost healed.

On April 11th there was a red line of lymphangitis, a temperature of 101°, and the finger was more painful. Gas was given again and the wound was opened up more freely on both sides of the finger and at the root of the nail; a little clear serum escaped. The temperature did not subside, and she developed red nodules very similar to erythema nodosum along the arm and a few on the legs, abdomen, and neck. Owing to nursing difficulties she was moved into hospital and the arm kept in a eusol bath. The temperature then became normal, and remained so from April 16th to 20th, when it again rose to 100° and on the 21st to 104.8°. On April 22nd the temperature was 99° in the morning and normal by evening, and remained normal until April 25th, when it reached 100° in the evening.

Sir William Willcox, to whom I mentioned the case, agreed that it was a case of rat-bite fever, though he had never heard of a case occurring as a result of a pig bite, and on his advice 0.6 gram of novarsenobenzene was given, after which the temperature fell to normal in twelve hours and has remained so. There was considerable desquamation of all the nodules and arm where the lymphangitis had occurred. Recovery was quite uneventful, except for an attack of urticaria two days after the injection.

Chelmsford. R. P. SMALLWOOD, M.B.

EXCESSIVE HAEMORRHAGE AFTER TOOTH EXTRACTION, DUE TO ACUTE LEUKAEMIA.

THE case here recorded, in which the extraction of a tooth was followed by excessive haemorrhage, resulting in death of the patient, seems of sufficient interest to warrant publication.

An unmarried girl, aged 17, was admitted to the Salford Royal Hospital on April 25th last as a case of excessive haemorrhage occurring after tooth extraction. The second left upper molar tooth was extracted on April 18th, and she had bled continuously from that time until her admission—that is, for seven days. She had never previously had a day's illness in her life. Menstruation had started the day before.

Condition on Admission.—She was very pale, anaemic, almost moribund. The mouth was septic. The tooth socket had stopped bleeding. Temperature 97° F., pulse 140, respirations 34. No other abnormalities were noticed at the time.

She was given rectal salines, digitaline, and mouth washes, and rallied slightly. The next day a transfusion of one pint of blood from her father was given, and there was immediate temporary improvement. Bleeding started again, however, in a few hours' time, but not much blood was lost before the heart suddenly failed and she died on April 26th at 7.30 p.m.

A necropsy revealed amongst other things multiple haemorrhages into the heart muscle, lungs, upper surface of the diaphragm, and suprarenals; intense fatty change in the heart, liver, and kidneys. The spleen was not enlarged and was macroscopically normal. A generalized slight enlargement of lymph glands was present. Free blood was present in the peritoneal cavity and there was a great deal of blood in and around the left tube and ovary (Graafian follicle especially); the condition of the left tube and ovary was such that in certain circumstances—for example, an abdominal section—it might quite easily have been mistaken for a ruptured ectopic pregnancy.

Stained sections of the liver and spleen were reported on as acute lymphatic leukaemia. A blood smear taken even seventy-two hours after death showed lymphocytes to be almost as numerous as the red cells.

The parents, convinced that the dental extraction had caused the girl's death, precipitated an inquest. At the inquest it was maintained that: (1) Death was due to acute lymphatic leukaemia. (2) There was internal haemorrhage, sufficient in amount and situated in such a way as to account for death quite easily. (3) It was impossible to say that the extraction had accelerated death, and probably it was a coincidence.

Mr. J. B. Macalpine, under whose care this case was, kindly gave permission to write this note.

W. C. D. WALMESLEY, M.B., Ch.B.,
House-Surgeon, Salford Royal Hospital.

Reports of Societies.

RESULTS OF THE OPERATIVE TREATMENT OF ENDOMETRIOMATA.

AT a meeting of the Obstetric Section of the Royal Society of Medicine, with the president, Dr. J. S. FAIRBAIRN, in the chair, Mr. CHARLES D. READ and Mr. FREDERICK ROQUES communicated a paper on after-results of the operative treatment of endometriomata—a study of forty-one cases.

In spite of the large amount of literature on endometriomata, the authors found but few references to the treatment of these tumours. They quoted Herd and Sampson, the latter author having reported 23 cases but given details of the results of treatment in only 10. A detailed study of the authors' cases followed. They were divided into five groups: (*a*) ovarian, 25 cases or 61 per cent.; (*b*) uterine, 11 cases or 27 per cent.; (*c*) abdominal scar, 3 cases or 7 per cent.; (*d*) recto-vaginal space, 1 case or 2 per cent.; (*e*) umbilicus, 1 case or 2 per cent. Tables were shown giving full clinical details in each of the 41 cases, with the treatment and the condition of the patients at the time of writing. The results of treatment in each group were then analysed. The ovarian cases fell into two groups: (1) Cases in which the growth had been excised from one or both ovaries or in which one ovary only was removed in its entirety; in other words, all ovarian tissue was not removed at operation. (2) Cases in which both ovaries were completely removed or in which complete removal was attempted, with or without concomitant hysterectomy. Of 14 patients in whom one ovary or part of an ovary was left 10 were cured, 2 improved, and 2 remained unrelieved. These two patients were later treated by more radical measures, bringing the total number of operations in the ovarian group to 27. Of 13 patients from whom all ovarian tissue was removed 10 were cured, 2 improved, and 1 remained unrelieved. The uterine cases were similarly divided into two groups. (1) Cases in which the growth was excised from the uterus. (2) Cases which were treated by hysterectomy—total or subtotal—with or without concomitant hysterectomy. In 2 cases the growth was excised from the uterus. One patient was cured, the other improved. Nine cases were treated by hysterectomy. The authors remarked that removal of the ovaries with the uterus did not influence the result in cases treated by hysterectomy, and suggested that the question of oöphorectomy in uterine endometriomata should be determined by the age of the patient and the degree of implication of the ovaries with the uterine growth. The remaining cases—3 abdominal scar, 1 recto-vaginal, and 1 umbilical—were treated by local excision. Comment was made upon the relatively low incidence of recto-vaginal tumours in this series. The results of the two forms of

treatment—conservative and radical—of 43 operations on 41 patients, were then reviewed. Of 21 patients treated conservatively 15 were cured, 4 improved, and in 2 symptoms persisted after operation. Of the 22 patients who were treated radically 19 were cured, 2 improved, and in 1 no relief was experienced. The most striking fact which emerged from these figures was the high "cure rate" of conservative treatment, which in the authors' opinion was the treatment of election in all patients under 38 years of age in whom the local conditions of the growth—for example, extensions involving the bowel—were not unfavourable. They again quoted Sampson, who reported three pregnancies among five patients treated by conservative operation. The advantages of local excision were that the operation was less severe and probably attended by a lower operative mortality, there was a possibility of subsequent pregnancy, and, usually, continuation of the menses. Against those advantages the chance of recurrence was to be weighed. This risk was more than justifiable in the young patient, whenever local conditions permitted. Only very occasionally in extensive lesions was complete clearance of the pelvis indicated, irrespective of the patient's age. For the older patient more extensive measures were recommended. The advantage claimed was the complete success with which they were attended, although the mortality might reasonably be expected to be higher. In the series of cases under discussion this consideration did not apply, as the mortality was *nil*. Post-menopausal retrogression of endometriomata was mentioned in connexion with the disappearance of the outstanding symptoms of dysmenorrhoea and menorrhagia. In patients near to the climacteric operation was only justifiable in those cases in which the tumour was causing the mechanical symptoms of pressure and intestinal stenosis. The value of radium in treatment was discussed, and the authors referred to one of their cases in which radium proved successful after three laparotomies had failed. They favoured the use of radium in selected cases, but thought it doubtful whether radium would ever be applicable to ovarian or to uterine endometriomata, for the reason that diagnosis, in many cases, was very difficult, in some cases almost impossible. In particular, the difficulty of excluding pelvic inflammation as an alternative diagnosis would make most hesitate to advise radium treatment for endometriomata of the ovaries or of the uterus.

The following factors influenced the method of treatment in any given case. (*a*) *The age of the patient.* The younger the patient the stronger was the indication for conservative treatment, except in large tumours with extensive infiltration of surrounding structures. (*b*) *The extent of the lesion.* This influenced the decision between "conservative" treatment, on the one hand, and "radical" and "radium" treatment on the other. Conservative treatment was indicated for a limited growth in young patients, radical operation for all extensive lesions in patients over 38 years of age, especially in the presence of mechanical symptoms. Radium was a useful adjunct in inoperable cases and in cases in which radical operation had failed. (*c*) *The site of the lesion.* Ovarian endometriomata lent themselves to both forms of surgical treatment depending on the factors already considered. Uterine endometriomata should be similarly treated, remembering the governing principles of age, extent, and parity. Conservative treatment was less frequently possible than in the case of the ovarian tumours. Endometriomata in the recto-vaginal space, if accompanied by uterine or ovarian involvement, demanded radical operative treatment. Localized tumours lent themselves to both local incision and radium therapy. Scar and umbilical endometriomata were satisfactorily treated by local excision. In these situations radium was a possible alternative; but its use had not yet been exploited.

A Gigantic Foetus.

At the same meeting Dr. E. LAWTON MOSS showed a specimen of a gigantic foetus. The head had been delivered with axis-traction forceps, and the shoulders by means of traction with a blunt hook. The foetus was stillborn, and immediately after delivery weighed 24 lb. 2 oz. The sub-occipito-bregmatic diameter of the head was 5½ in., and the length from vertex to heel was 35 in. The placenta weighed 4 lb. The mother made an uneventful recovery. Dr. *Lawton Moss* pointed out that the enormous size of the foetus could not even in part be attributed to post-maturity, since the mother started labour a few days before her expected full term. A search through the English references had failed to reveal any reference to a foetus so large as the one shown. Dr. HERBERT SPENCER, in the discussion, suggested that the weight of the foetus was a record not only for English cases, but for all cases of this kind published in any country.

Vulval Fibro-adenoma.

Mr. A. J. WRIGLEY showed sections of two cases of adenomatous tumour of the vulva which had the histological characters of a fibro-adenoma, such as is commonly found in the breast. He said that these tumours in the vulva were very rare, or at any rate very rarely described, and as their anatomical position excluded the possibility of their arising in Bartholin's gland, and because their histological appearance differed from that of a sebaceous adenoma, he looked upon them as a distinct type of fibro-adenoma.

Pelvis of an Australian Aboriginal Woman.

The SECRETARY read a paper by Professor Cleland and Drs. Dawson, Wallace, and Hackett, the object of which was to record accurate measurements of the bony pelvis of an aboriginal woman of Australia. The measurements were taken from a pelvis removed post mortem from a woman who had died during labour. In comparison with the pelvis of a normal white woman, the most striking differences in the pelvis described were a narrow subpubic angle, and a marked diminution in the transverse diameters of the brim, the cavity, and the outlet. The pelvis, as a whole, was funnel-shaped.

A Method of Inducing Labour.

Mr. G. F. GIBBERD read a short communication recording the results of thirty cases of induction of labour undertaken by means of the introduction into the uterus of a sterile animal bladder containing glycerin. Although the method had disadvantages and dangers shared by other instrumental methods of induction, it had the one advantage that, compared with other methods, its use was attended by a considerable reduction in the time interval before the onset of pains.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of the Aberdeen Medico-Chirurgical Society on June 6th, the president, Professor ALEXANDER LOW, in the chair, a demonstration of specimens was given in the pathology department, Marischal College. Professor THEODORE SHENNAN Dr. JOHN GRAY, and Dr. R. D. LOCKHART described the exhibits.

Among the post-mortem specimens shown by Professor Shennan and Dr. Gray were two cases of cancer of the body of the pancreas, neither involving the head and both showing extensive metastases to liver, mesenteric border of small intestine, and omentum; a specimen of acute phlegmonous gastritis showing inflammatory oedema and suppuration in all coats of the stomach wall, most extensive in the submucosa and implicating the lower part of oesophagus and upper duodenum, with Gram-positive diplococci present throughout the lesions and no evidence of antecedent ulceration or infective foci; a case of primary cancer of the left kidney, infiltrating the organ diffusely and enlarging it greatly; a case of periarteritis nodosa terminating in uraemia; a case of active glandular tuberculosis in a female, aged 72, with cervical and mediastinal glands increased to the size of walnuts but with only slight pulmonary infiltration; and specimens demonstrating widespread metastases in the myocardium, mediastinum, lungs, liver, gall-bladder, abdominal glands, bone, and pituitary gland, from a squamous epithelioma arising in an indolent leg ulcer in an individual with a positive Wassermann reaction.

Dr. Lockhart showed a dissected preparation of a rare condition, complete double aortic arch in the adult; two brains showing symmetrical psammomata of the choroidal plexus; the brain of a rabbit 4 days old, with hydrocephalus; an infantile form of appendix, lying behind the peritoneum and reaching along the ascending colon to the hepatic flexure; radiograms and photographs illustrating the position of the scapula in trapezius paralysis; and a series of radiograms demonstrating the relative amount of movement occurring in the normal shoulder-joint during elevation from the dependent to the horizontal position and from the horizontal to the vertical.

Reviews.

THE SCIENCES AND PHILOSOPHY.

CONSIDERING how much that was obscure in Nature has been explained by science, it may seem excusable to believe, as some do, that science will in due time solve for us the mystery of the universe. Such a belief, without doubt, acts as a stimulus to research, and on this account it would seem to be mere gratuitous meddling to attempt to undermine it. There is, however, another aspect of the question, and it is very ably discussed by Professor J. S. HALDANE in the Gifford Lectures for 1927–28, under the heading of *The Sciences and Philosophy*.[1] Professor Haldane has reflected on this question for some forty or fifty years, and, being a scientist, he approaches the subject in a scientific spirit and, one may suppose, with a leaning towards science. A study of his lengthy argument leads to the conviction that the advances made by science have brought us no nearer the solution of the mystery of Nature than were the contemporaries of Job; in fact, the mystery appears to deepen with each new discovery. This conclusion is of no great practical importance, but another deduction is drawn, the practical importance of which cannot be exaggerated. It is shown with a considerable degree of plausibility that the gross materialism which is a characteristic of the present time has its roots in a tendency to allow conventional and limited scientific conceptions to do duty for philosophy or, as the author defines it, the conception of the whole as distinguished from a mere part of the reality of Nature. From this tendency arose the mechanistic conception of Nature elaborated by Descartes and largely held in a semi-conscious fashion at the present time. Mechanical and physico-chemical forces appeared to explain so much that men came to think that all would ultimately be thereby explained. This was an error, for it omitted all consideration of the essential feature of living organisms—namely, the power of developing and maintaining their specific structure and of reproducing it from generation to generation. This fact is inexplicable on a purely physico-chemical theory, which is thus shown to be merely a conventional and limited conception of reality. The same is true of the vitalistic theory initiated by Stahl—namely, that all could be explained by assuming the presence of a vital principle or soul, having an independent existence in the organism and controlling the physico-chemical processes of the body. A very essential reality is omitted in this theory, one which is strongly emphasized by Professor Haldane as marking the distinction between biology and psychology as separate sciences. In unconscious living beings, such as plants, the vital reactions are determined solely by present conditions; whereas in conscious organisms ideas of the past and the future and a consciousness of interest and values are introduced as a new element—and not only the interest of the organism concerned, but also that of his fellows, present and to come. The biological or vitalistic theory, therefore, is, like the mechanistic theory, inadequate as a conception of the whole of reality. The separation of the sciences in different watertight compartments is doubtless practically convenient; the engineer need take no account of biological forces in carrying out his engineering schemes, and the surgeon can disregard psychological subtleties when performing a major operation These are arts which call merely for a restricted and conventional view of natural forces; but the art of living needs something more than restricted views, and nothing will avail except philosophy or the "conception of reality in its totality." If an attempt is made, as above indicated, to elevate any one of the sciences into the position of a philosophy, materialism is the inevitable result. The bearing of these facts on questions of general and technical education is obvious, and is clearly expounded in the Gifford Lectures. What, then, it may be asked, is the philosophical view of life and the universe ultimately reached by Professor Haldane? The reader is recommended to procure the book and study this, the most important part of the work, for himself.

HYDROGEN-ION CONCENTRATION.

THE volume entitled "*p*H in Biology"[2] by MM. MARCEL VERAIN and JEAN CHAUMETTE prompts us to reflect that aesthetic considerations have not always weighed in the choice of scientific symbols. It is, however, too late to complain that *p*H is lacking in the picturesque. *p*H has arrived; and in no field has it arrived with such assurance as in the domain of physiology. The hydrogen ion—most diminutive of molecular species known to chemistry—holds the stage, directing the activities of enzymes, controlling the restless forces of metabolism, and shaping that destiny which is thrust upon each living organism by the environment in which it finds itself. A scientific symbol is justified by works, not by faith. It is useful only in so far as it may permit a more economical description of observed phenomena. By this token *p*H has earned a place in the vocabulary of every biologist. At the same time, it has its defects. *p*H, on the one hand, represents a direct experimental observation made with appropriate instruments. On the other hand, it stands for the whole body of theory of electrolytic dissociation which is now the foundation of the treatment of all aqueous systems in which biology is interested. The dual role has proved difficult to sustain. Moreover, it is to be remembered that *p*H involves a scale of reckoning which is foreign to most of us, requiring, as it does, the mental habits of a slide-rule.

For all these reasons biologists may properly seek instruction in the mysteries of the hydrogen ion. Tempted by the comprehensive title chosen by the authors, they will be liable to disappointment unless they have been already warned by the modest dimensions of the book. This is not a wide and general survey of the significance of hydrogen-ion activity in vital phenomena. The main part is devoted to an exposition of the fundamental principles upon which the theory of electrolytic dissociation is based, particular attention being directed to those weak acids and bases which figure prominently in physiological systems. The presentation is simple and attractive, but it seems a pity that the revolution in the treatment of ampholytes which we owe to Bjerrum and Bronsted should have been ignored. The inclusion of this is urged, not because it is recent knowledge, but because it leads to a definite simplification of treatment. Detailed description is then given of the various methods in common use for the determination of the hydrogen-ion concentration of fluids, particularly of blood. For the rest, there are chapters on the hydrogen-ion concentration of the blood and of the cerebro-spinal fluid, and a catholic section of fourteen small pages roaming without aim over the fields of digestion, bacteriology, and vegetable physiology.

As a contribution to a series of monographs on practical medicine this book presumably seeks to do service to the medical profession. This it does within the restricted field covered; but we feel that the biological section suggests a narrow interest which does scant justice to so ambitious a title. This is a pity, for many seek an understanding of these matters.

[2] *Le pH en Biologie.* Par Marcel Verain et Jean Chaumette. Préface du Professeur E. Darmois. Paris: Masson et Cie. 1928. (5¼ × 7¾; pp. viii + 150; 20 figures. 16 fr.)

THE SEXUAL LIFE OF SAVAGES.

UNTIL fairly recently the tendency both among anthropologists and psycho-analysts was to keep strictly to their respective fields, the former to a study of the variations of custom and belief among peoples of diverse races, traditions, and cultures, the latter to a study of the springs of behaviour in normal and abnormal persons in civilized society. Lately, however, a few workers in these sciences have invaded each other's territory, and found, to their surprise, that they felt almost at home. Psycho-analytic theories which deal with the significance of the sexual life in the formation of character traits, and the determination of behaviour—in particular, theories which define in exact terms the psychological mechanisms involved—have been criticized on the ground that they are valid, if at all, only in relation to a particular culture and family structure, and cannot, without considerable modification, be used to

interpret the behaviour of persons living in another cultural environment involving an entirely different system of family relationships. *Totem and Taboo* by Freud, *Dream and Myth* by Karl Abraham, and a number of studies in *Essays in Applied Psycho-Analysis* by Ernest Jones, represent attempts on the part of psycho-analysts to meet this criticism and to relate psycho-analytic theory to that portion of the world's population which does not inhabit Vienna, Budapest, New York, and London. That the anthropologists, too, have gained something by a study of the psycho-analytic method is evident from much of their recent work—above all, from the work of Professor BRONISLAW MALINOWSKI. Professor Malinowski, it may be said, has visited the well of psycho-analysis, but has drunk with restraint and discrimination. His *Sex and Repression in Savage Society* owes much to the work of Freud and his disciples; it represents, however, as cogent and intelligent a criticism of that work as has ever been made. In his latest book, *The Sexual Life of Savages in North-Western Melanesia*,[3] he does not concern himself so strictly with theory; he is content rather to provide material for the theorist in the form of a vivid and detailed account of custom, thought, and ritual, especially in relation to sexual play, courtship, marriage, and family life among the Trobriand islanders, one of the Melanesian peoples of British New Guinea. The interdependence of sexual, matrimonial, and family relationships can be adequately understood only by a study of their variations under different cultural conditions.

Professor Malinowski's book falls roughly into two parts: the first records the life-history of the average Trobriand islander, and includes what must be the most precise and unemotional account of the manifestations of infantile sexuality that has appeared in the English language. It is interesting to learn that pre-nuptial licence, which appears to be general in Melanesia, leads inevitably to the development of monogamous interest and finally to marriage. The early love affairs represent a form of courtship, a process of trial and error, in which promiscuous unions gradually become restricted and give place to permanent, legally sanctioned marriage. According to Professor Malinowski, pre-nuptial licence among the Trobriand islanders leads only very rarely to the production of illegitimate children, and women relatively prolific after marriage remain sterile throughout the period of adolescent liaison. Beyond stating categorically that the natives use no form of contraception Professor Malinowski makes no attempt to account for this extraordinary phenomenon, holding that it demands skilled medical investigation. He insists throughout, though not very convincingly, that the Trobriand islanders have so far failed to associate reproduction directly with the sexual process. In the second part of the book Professor Malinowski makes a detailed study of erotic folklore, games, stories, and songs, and considers at some length the psycho-analytic correlation between myth, day-dreams, and other forms of wish-fulfilment fantasy, and the structure of the family in a matrilineal society. It remains only to add that the book is beautifully written, and one is continually reminded of the fact that Bronislaw Malinowski is a countryman of Joseph Conrad.

CARDIOLOGY.

A CONSIDERABLE number of alterations and additions have been made in the second edition of Dr. REID'S book, *The Heart in Modern Practice*,[4] though the general character of the first edition, which was noticed in our columns on November 17th, 1923, has been retained. Perhaps the best part of the book is the arrangement of the subject-matter, which is presented in five sections. The first deals shortly with anatomical and physiological considerations and methods of examination, and contains a classification of heart disease on the lines of that recently published by the American Heart Association. The three succeeding sections consider heart disease from the etiologic, structural, and functional points of view, while the fifth section deals with treatment; to this are added appendixes giving diets and occupations suitable for cardiac patients, and a series of illustrative case reports.

The aim of the author is to present the best of the new knowledge with that less recently acquired, and there are many references to modern work throughout the text. The book, however, is patchy, and the amount of space devoted to some subjects is hardly in keeping with their importance. Thus, for example, coronary infarction is dismissed in little more than one page, while extra-systoles receive no less than twenty-two pages.

Again, the important subject of failure with congestion is given scant treatment, and neither failure nor venous congestion appears in the index. Though it is true—as the author points out in his preface, foreseeing such criticism—that certain subjects do lend themselves to a brief presentation, while with others clearness demands greater space, yet in a manual for students and physicians the brief statement of important signs and symptoms is too often inadequate to make the reader realize their significance. We feel that though the author has a good story to tell, he does not make his points sufficiently clear.

AMERICAN MEDICAL WAR HISTORY.

THE fourth volume of the history of the Medical Department of the United States Army in the world war has been prepared by Major ALBERT S. BOWEN, under the title of *Activities Concerning Mobilization Camps and Ports of Embarkation*.[5] Other volumes of the series embody data bearing closely on this subject, but not covering it completely. The student of military medicine is bound to be interested in a work that describes and discusses the method by which a large army was mobilized and its raw material trained. It is being realized more and more that if the personnel of an army is to withstand the strains of modern warfare the medical profession must play an important part in its mobilization and training, in the selection of fit men for the more arduous duties, and the placing of unfit men in positions where they may be of maximum benefit to the force. Only in this way, moreover, can the admissions to hospital, invalidism, and pensions be kept down to the minimum.

The volume under review deals with two classes of camps—divisional and miscellaneous—which were used for the mobilization of the fighting forces. The divisional camps comprised the tent group for the National Guard divisions, and the cantonment group for the National Army divisions; the miscellaneous group comprised the special camps intended for embarkation purposes or for mobilizing and training special troops. In describing the procedure during the mobilization and training period (August 25th, 1917, to November 11th, 1918) it is pointed out that the general officer commanding each of the sixteen National Army cantonments was required not only to organize his division, but, for the ultimate purpose of receiving and training men for the tactical divisions, to establish a depot brigade, which from the point of view of the medical department became an important part of camp organization. There follows a detailed account of the medical administrative officer's duties, which are grouped thus: (*a*) prevention of the introduction and spread of communicable disease in the cantonment area; (*b*) administration of prophylactic inoculations; (*c*) sanitation of the cantonment area; (*d*) physical examination of drafted men; (*e*) organization and equipment of sanitation units; and (*f*) instruction and training of medical department personnel. It has been a commonplace of military history that whenever a large force has been specially raised any personnel not required for the combatant units has been considered good enough for the medical services. This same error of organization occurred in the American army, and it was only after the lapse of time that commanding officers came to realize that the care of the sick and wounded was too important and

[4] *The Heart in Modern Practice.* By William Duncan Reid, A.B., M.D. Second edition, revised and enlarged. London: J. B. Lippincott Company. 1928. (Med. 8vo, pp. xii + 466; 81 illustrations. 25s. net.)

[5] *The Medical Department ... ...ny in the World War.* Prepared under the ... M. W. Ireland. Vol. iv: *Activities Concer... ... and Ports of Embarkation.* By Major Albert S. Bowen, *M.C.* Washington: U.S. Government Printing Office. (Sup. roy. 8vo, pp. vii + 494. 1.75 dollars.)

too arduous a task to be delegated haphazard to whatever personnel remained when the combatant units had made their selection.

Four chapters of the book are devoted to a detailed description of the arrangements peculiar to National Army cantonments, and to National Guard camps, while the concluding two chapters, based on the *History of the Office of the Surgeon, Port of Embarkation, Hoboken, N.J., and Newport News, Va.*, give a broad survey of the intricate administrative measures required during embarkation and disembarkation of troops. The mass of facts presented in these chapters is likely to prove uninteresting to the non-specialist student, who will find it difficult to extract from them any broad principles; but the placing on record for all time of the intimate details of the work done in the various camps must command our respect. The officers responsible for the medical organizations in the late war will, in the nature of things, give place to others; and while it is earnestly hoped that the next generation will be spared the horror of war, the record under review will, if the occasion ever arises, prove of inestimable value in helping the medical officer of the future to avoid a repetition of past failures and to build up on the accumulated experience of the past.

NOTES ON BOOKS.

THE sixth edition of Sir EDWARD HENRY'S *Classification and Uses of Finger Prints*,[6] which originally appeared in 1900 at the request of the Indian Government, and subsequent editions at the instance of the Secretary of State for the Home Department, gives an account of the development of this now familiar method of identification. As long ago as 1823 Purkinje, in his inaugural dissertation at Breslau, advocated its introduction, giving nine standard types and suggesting a system of classification. Later Sir William Herschel of the Indian Civil Service, impressed by the amount of false personation in the courts, attempted, but without success, to get their means of fixing identity adopted. In 1894 Sir Francis Galton's further elaboration of the system was considered by a special committee appointed by the Home Secretary, Mr. Asquith. In 1897 the method of classification of finger marks, constructed by the Inspector-General of Police, Lower Provinces, Mr. (later Sir) E. R. Henry, was recommended by a committee as superior to Bertillon's more complicated anthropometric system (1883), and was officially adopted before 1899 in India; in 1901 the identification by finger prints, without the combined primary classification by Bertillonage, as recommended in 1894, was adopted in this country. In this work the method of taking and the necessarily elaborate system of classifying finger prints are clearly set out, and very copiously illustrated by more than 200 diagrams.

The April number of the *Guy's Hospital Reports*,[7] which contains ten articles, opens with a pleasantly written essay, the outcome of Professor G. W. Nicholson's thoughts and reading for thirty years, on the philosophy of natural science. This is followed by a valuable and well-illustrated article on the etiology and significance of extra-systoles, based on analysis of 500 consecutive cases at the cardiographic department, by Dr. Maurice Campbell; they were recorded in about one-fifth of the patients, and were supraventricular only in 30 per cent., ventricular only in 40 per cent., both in 10 per cent., and in 20 per cent. interrupted auricular fibrillation. The editor's name appears over two conjoint papers: with Dr. J. F. Venables of the New Lodge Clinic he shows that, like the duodenal ulcer diathesis, the gastric ulcer diathesis is characterized by the presence of hyperchlorhydria. In reporting two cases of gastric ulcer associated with congenital diaphragmatic hernia, he first points out that there are only two such cases on record—one by Bright in the first volume of these *Reports*, and the other by Key of Stockholm in 1924. Mr. Philip Turner contributes two papers; he describes two cases of multiple rapidly growing soft fibro-adenomata of the breast in girls aged 14 and 15 years, and for comparison one of true hypertrophy of both mammae in a woman aged 25 years. Together with Mr. Nils Eckhoff, the surgical registrar, he gives the results of treating inguinal hernia by simple excision of the sac. There are three articles, replete with analyses of cases, by Mr. Ralph Thompson, from the genito-urinary department, dealing with horseshoe kidney, solitary kidney, and the formation of calculi in the kidney and ureter. A case of total cystectomy in which some investigations on urinary secretion were made is described by Mr. H. L. Maister, Mr. W. H. Ogilvie, and Professor M. S. Pembrey.

One of the great advances in the prophylaxis of malaria has been the recognition that the problem is a local one. It is impossible to formulate any general principles which are applicable everywhere; instead local conditions must be studied on the spot. To this end the Institute for Medical Research inaugurated a series of mosquito surveys in South Africa. The results of the first survey (Part I) received a notice in this *Journal* on June 2nd last year (p. 949). Part II, *A Mosquito Survey of Certain Parts of South Africa, with Special Reference to the Carriers of Malaria and their Control*,[8] by ALEXANDER INGRAM and BOTHA DE MEILLON, which has now appeared, deals for the most part with the low veld district of the Eastern Transvaal, one of the most malarious regions in the Union of South Africa, during September–November, and secondly, with observations made during a tour through the Eastern and Northern Transvaal during the malarial season. Those interested in the epidemiology of malaria will do well to consult this paper.

The official directory for 1923 of the Association of British Chemical Manufacturers, entitled *British Chemicals: Their Manufacturers and Uses*,[9] contains, in addition to particulars of the 120 firms who compose the association, a classified list of British chemicals, with a note on their uses and applications. The names of these chemicals are furnished in five languages in addition to English—namely, French, German, Spanish, Italian, and Portuguese—the idea being that the volume may be of use to commercial attachés, consular officers, and trade commissioners throughout the world, and so widen the British chemical market. Another useful section gives proprietary and trade designations, with a chemical description of the products and the name of the manufacturer. Medicine figures as the sole or as one of the principal uses of a very great number of the preparations. Among the acids alone some forty are given a medical use, and nearly as many of the sodium compounds. The volume is a directory and also a technological dictionary, as well as an impressive index to post-war enterprise in this important field.

The second edition of the book containing tables of doses for roentgentherapy,[10] by Professor Dr. F. VOLTZ, differs from the first in three respects: the text has been extended, the diagrams illustrating the text altered, and the dosage tables, which are the essential feature, have been considerably expanded. The tables should be very useful to those who use *x* rays for therapeutic purposes, as a reference to them saves the trouble of working out depth doses. The letterpress deals with general rules—this covers dispersion, absorption, and scattering of *x* rays—with various points, physical, biological, and so on, affecting dosage, and with methods of measurement.

PREPARATIONS AND APPLIANCES.

AN X-RAY PLANT FOR SHIP SURGEONS.

WE have received from Messrs. Philips Lamps Limited the following particulars of a portable *x*-ray outfit, known as Philips "Metalix-Portable," which they claim is suitable for use at sea. A trolley table carries the entire outfit, and accommodates a small rotary converter, which supplies the necessary alternating current to the apparatus from the ship's electric supply. The outfit is provided with a metal-clad *x*-ray tube mounted on adjustable legs, by which means it can be accurately centred over the patient, the high-tension current being fed through two specially insulated shockproof cables. While in operation the outfit can be handled with perfect safety. The patient experiences no sensation, and nothing to indicate that a pressure of some 65,000 volts is being generated within such a small compass. The apparatus is completely enclosed, and no special knowledge is required to operate it.

AN IODINE "PEN."

We have received from Messrs. Clay and Abraham, Ltd. (87, Bold Street, Liverpool), a specimen of their Canda iodine pen. This handy little appliance, as its name implies, is a tubular receptacle for tincture of iodine. The mouth of the glass phial is drawn out into a point so that the iodine can be applied drop by drop without the need of a brush. A screw top with washer prevents leakage, and further security is given by a metal container. The price complete is 1s. 2d., post free.

TREATMENT OF MALIGNANT DISEASE BY RADIUM.

CAVENDISH LECTURE BY PROFESSOR CLAUDE REGAUD.

THE Cavendish Lecture, under the auspices of the West London Medico-Chirurgical Society, was delivered at Kensington Town Hall on June 21st by Professor CLAUDE REGAUD, director of the physiological laboratory of the Radium Institute, Paris. The title was "The progress and limitation in the cure of malignant diseases by radium." Professor Regaud exhibited many tables of statistics of cases treated at the institute, which were not, however, very easy to follow, and he spoke of "complete cures" when it was not quite clear what criterion of cure had been adopted. In one part of his lecture he referred to a five-year freedom from recurrence as though this were equivalent to cure, and yet apparently cases which had been treated as recently as 1926 were recorded as cures.

Methods of Radium Application.

Professor Regaud began by remarking that the chief advances in radium therapy (or as he preferred to call it "curietherapy") had resulted from an increased knowledge in two directions: the physical properties of radio-active substances, and radio-physiology in general; in particular, the behaviour of cancer treated by radiation. Various methods of attacking cancer by radium had been followed these last thirty years. One method might be dismissed at once as having no proved value—namely, indirect approach by way of the blood stream. The three main procedures had been internal, interstitial, and external curietherapy. The first consisted in the introduction of radium tubes into the natural cavities or channels. In general this had not been very successful except in the treatment of squamous-celled cancers of the uterus. Here Professor Regaud gave statistics of uterine cancer treated in this manner at the Radium Institute in Paris, and claimed for it a high percentage of cures. The second method was what he called radium puncture—namely, the introduction of radio-active needles into the substance of the tissues. Radium puncture had been perfected at the Paris Radium Institute, where treatment by numerous foci of weak intensity was made a regular method. It was reserved, however, for certain cancers of small size, cutaneous or subcutaneous, such as certain varieties of cancer of the breast, and especially cancer of the tongue. In this limited field the procedure gave good results, despite the difficulty of ensuring a uniform irradiation and the possibility of radium necrosis which sometimes complicated the treatment. His institute was by no means wedded in principle to this procedure. Maxillary cancers had been treated by resection of the superior maxilla followed by packing the cavity with numerous small radio-active foci. The use of radium combined with surgery offered a promising field, and in cancer of the rectum the employment of surgical radium puncture and excision seemed to give better results than excision alone. Of cancers of the tongue and floor of the mouth treated at the Radium Institute between 1920 and 1926, a complete clearing up was reported in 82 out of 367, while 193 had to rank as complete failures. The method adopted was again that of numerous weak radio-active foci, the tubes being retained in position by gauze packing. The lecturer also described a method of applying radium externally by embedding the tubes in plastic supports of any desired shape or dimensions. This method had resulted in great progress in treatment of cancers of the skin, lymphatic glands, and mouth, other than the tongue. Statistics for cancer of the lips treated in this way between 1920 and 1926 showed that in 62 operable cases a complete cure was effected by radium in 56; out of 22 cases of doubtful operability there were 16 complete cures, and out of 28 inoperable cases, 4 cures.

Telecurietherapy.

When the depth of the cancer necessitated a screen distance greater than 6 to 8 cm., the dose of radium required, instead of a few hundred milligrams, was of the order of grams. It was then necessary to surround the radiating surface with lead several inches thick in order to protect the body of the patient and others. These considerations during the past six years had led to the construction of a source of gamma radiation acting at a distance, in the same way as the x-ray tube. Telecurietherapy, or irradiation of the tumour at some distance from the body, required the use of radium in bulk, and its use must always be limited by the scarcity and high price of the element. It had been employed in the treatment of deeply seated cancers. In actual procedure up to the present, not more than 4 or 5 grams of radium had been used, and with this a screen distance of 10 to 12 cm. could scarcely be exceeded; with greater distances the time occupied in treatment would be too long. If only radium were more plentiful it would be possible to develop this method, and the relative values of roentgenotherapy and curietherapy in the treatment of malignant disease would be greatly altered and the value of the latter enhanced. Professor Regaud illustrated by diagrams how a radium source of the strength indicated was enclosed in a lead box with walls 6 cm. thick, suspended from a supported beam, and placed in position over the patient for the treatment of cancer of the uterus.

Radio-physiological Investigation.

In spite of the fact that it had been again contended recently that radiation acted on cancerous tissue indirectly, the direct effect of the rays on the cells appeared to him to be established beyond serious criticism. The central problem of radiotherapy consisted in destroying the cancer cells through the whole extent of the infected area. There were two methods which could be employed. One was to give such a dose of radiation that all the living cells in the treated region were destroyed; the other—much more interesting and important—was to take advantage of the differences of the cells in respect to radio-sensitiveness and to cure the cancer by a cell dissection. This procedure, which had received the name of selective radiotherapy, depended upon a greater radio-sensitiveness of the neoplastic than of the normal cells. The difference should be sufficiently great to permit the toleration of those inequalities which were by reasons of geometry unavoidable in the irradiated area. Cancers differed widely in their degree of radio-sensitiveness; lymphosarcoma, for example, provided its dimensions were limited, could nearly always be sterilized, whatever its situation, because of its radio-sensitiveness, though the cure was unfortunately only local. Radiotherapeutic methods owed their utter powerlessness in certain cases not so much to the absolute radio-resistance of the neoplasm as to the great radio-sensitiveness of the surrounding tissues. Time did not permit the lecturer to deal with the reasons for the difference in radio-sensitiveness, but he indicated how the two factors, intensity of radiation and time of application, could be altered so as to get nearer to the desired effect. By using weaker doses spread over a longer time effects could be obtained which varied greatly from those forthcoming with strong doses given for a more limited time. Touching upon the association with radium therapy of the Blair Bell method of chemotherapy, the lecturer said that it was premature to draw conclusions from this research, but it was not impossible that it would produce important practical results, and once again experiment might set aside the limits apparently imposed upon the radiologist by Nature herself.

General Conclusions.

Summing up his general conclusions, Professor Regaud said that among the various procedures for applying radium the method of radium puncture should survive, though in a limited field. Radium combined with surgery still offered promise for further research. The employment of radium by placing it in the natural cavities appeared to have reached the limits of its usefulness, except in the uterus. Substances of plastic material were of value in the treatment of cancers of the skin and in some subcutaneous tumours. Telecurietherapy was encouraging in the treatment of deep-seated cancers, but was limited

by the scarcity of radium. On the radio-physiological side it remained to make the most fruitful investigations, and if means could be found to increase the narrow margin of radio-sensitiveness which lay between normal and *cancerous tissues it would constitute a momentous discovery.* A judicious exploration of the time factor had enabled the treatment of squamous-celled cancer to be greatly facilitated. By persevering in this line of research fresh progress would be made. Nevertheless, the fact could not be disguised that there was one obstacle which would always lie in the path of local radiotherapeutic methods—namely, the lack in certain cancerous cells of sensitiveness to radium, leading to widespread local extension and dissemination of the disease. The treatment of cancer by x rays and gamma rays had made great progress. Nevertheless, the method was limited. Radium was not a panacea for cancer—far from it. The public, and even medical men, did not always realize the serious difficulties which were encountered in its use. Therefore, while awaiting further developments in the radium treatment of cancer, the first reliance must be upon early diagnosis and prompt treatment.

MEDICAL CLUBS AND SOCIETIES.

MACALISTER LECTURE BY SIR HUMPHRY ROLLESTON.

To a gathering at the London Temperance Hospital, under the auspices of the London Clinical Society, on June 20th, Sir HUMPHRY ROLLESTON, Bart., G.C.V.O., delivered the third annual lecture in memory of Sir John MacAlister, the secretary of the Royal Society of Medicine. The subject of the lecture was "Medical friendships, clubs, and societies."

Sir Humphry Rolleston began by mentioning four men—three of them medical men, and the fourth J. Y. W. MacAlister—who, differing widely in their circumstances, illustrated some points in common, especially a manifest love for their fellow-men, the association of this charity with a like affection for books, and an appreciation of the value of clubs, societies, and libraries for professional life and progress. The first was Conrad Gesner, of the sixteenth century, who "kept open house for all learned men who came into his neighbourhood"; the second was Sir Thomas Browne, the author of *Religio Medici*, a book-lover and a philosopher, with a wide circle of friends and acquaintances; and the third was Sir William Osler, scholar-physician, teacher, humanist, a man thoughtless of self, and in sympathy with young and old, with the faculty of rapidly forming friends and of keeping them. As for MacAlister, a very clubbable man, the lecturer briefly sketched his career, and his great work for the Royal Society of Medicine and for the improvement of libraries.

Medical Clubs.

The lecturer went on to speak of the various medical clubs in London, some of them of a private, almost a family character. At the Royal College of Surgeons there was a Council club, and the Royal College of Physicians had a Fellows' club. The United Hospitals Club kept green the former close proximity and association of Guy's and St. Thomas's. Edinburgh also was rich in medical clubs of a convivial character. Sir Robert Philip had told him about the Harveian Society of Edinburgh, also called the Circulation Club, founded in 1782, with twenty members. The founder was Andrew Duncan, sen., and the threefold intention was to commemorate the discovery of the circulation, to promote good fellowship, and to foster experimental research. Another Edinburgh club, the Aesculapian, originally a supper and subsequently a dining club, was founded in 1773. It met quarterly, and was composed of 22 members chosen from among the Fellows of the Royal Colleges of Physicians and Surgeons of Edinburgh. A remarkable feature of this club was the devotion of the secretaries, for between 1773 and 1823 it had but five, an average tenure of twenty-three years. A more recent club, but now extinct, in Edinburgh was the Round Table, which flourished from 1868 to 1895. In Dublin, again, there were many clubs. The Medico-Philosophical Society, founded in 1756, was occupied at first with learned papers, but later it underwent a change, and the character of its meetings became entirely festive. In May, 1831, it was extinguished, to be revived in 1856 under its original name, as a dining club, sometimes jocularly dubbed the "Philo-oesophageals," the business being confined to the reading of the minutes of the previous meeting, which merely recorded the locality of the dining room and the names of the banqueters. The membership was limited to twelve.

Certain clubs developed into medical societies with a formal constitution. The lecturer mentioned the Leeds Medical Club, founded in 1862 by Clifford Allbutt and others. This club met until December, 1872, when it adjourned *sine die* in favour of the Leeds and West Riding Medico-Chirurgical Society, which flourished to this day. A body which represented the transition between a club and a society was the Association of Physicians of Great Britain and Ireland, started in 1907, largely under Osler's influence. It was composed of 250 members actively engaged in the teaching of medicine or in research, and met for two days once a year in university towns or towns the seat of recognized medical schools.

Medical Societies.

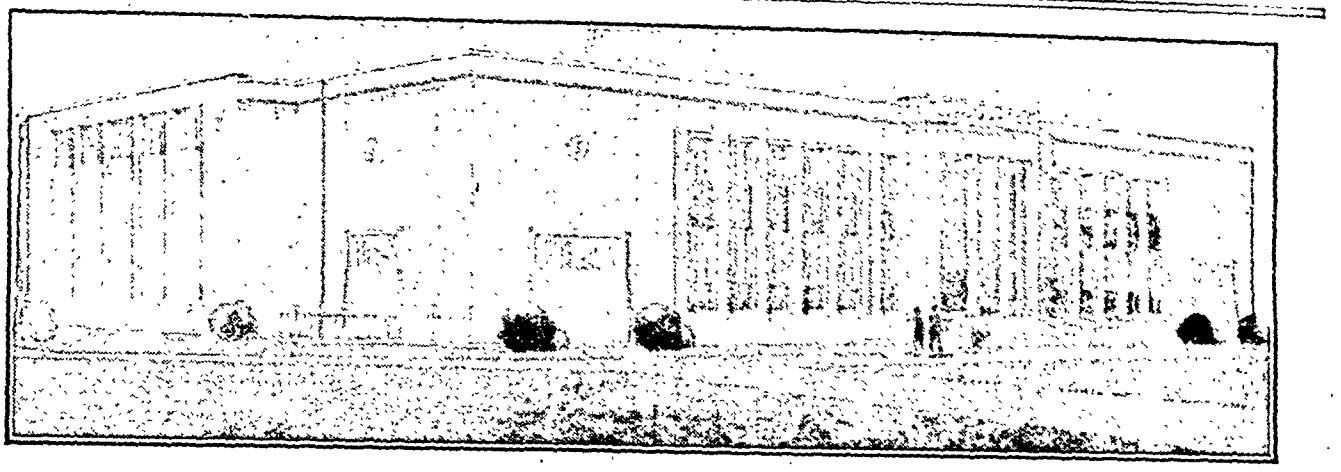
The medical society, the lecturer continued, supplied some of the essentials of post-graduate education; it offered also a legitimate means of intra-professional advertisement, and enabled young men to make themselves known to their older and better-established, but not necessarily better-equipped, brethren. The germ of the medical society in this country might be regarded as the meetings, beginning about 1649 in Oxford, of the "Philosophicall Clubbe." Many of the members, but by no means all, were physicians, and their object was the study of science in which medicine was to a certain extent included. The earliest medical societies proper were simply committees which published medical papers. After mentioning the early history of medical societies in Scotland, the lecturer sketched the growth during the second half of the eighteenth century of quite a number of medical societies in London and the provinces. John Hunter, with George Fordyce, founded the Society for the Improvement of Medical and Chirurgical Knowledge. More than one of these early societies bore much the same name as the present Medical Society of London, which was founded in 1773, and in consequence confusion might easily occur. The Medical Society of London was at first limited to 30 physicians, 30 surgeons, and 30 apothecaries, as the general practitioners were then called. The Medical and Chirurgical Society split off from this body in 1805, and rather more than a century later became the Royal Society of Medicine.

In the formation of provincial medical societies in the latter part of the eighteenth century the example appeared to have been set by Warrington; others followed at Colchester, Plymouth, Leicester, Halifax, St. Helens, and Nottingham. All these were formed between 1774 and 1828. The Gloucestershire Medical Society, which was spoken of as the Fleece Medical Society, from the name of the inn in which it met, was favoured by Edward Jenner in 1789 with "remarks on a disease of the heart following acute rheumatism, illustrated by dissections"—perhaps the earliest occasion, or one of the earliest, on which rheumatic heart disease was recognized. The lecturer also glanced at students' medical societies, in London, Edinburgh, and Glasgow. America was rich in this product; at Harvard there were more than a dozen such medical students' clubs, which were named frequently by letters from the Greek alphabet.

Libraries.

Sir Humphry Rolleston concluded with a few words about libraries. Like clubs, he said, libraries provided welcome meeting-places for making new acquaintances along many lines of thought and cementing old attachments. There the living could gain an intellectual and intimate affection for the heroes of the past. "To spend hours in a library excites feelings of pity, sadness, and humility, for there are many and bulky tomes on which their authors expended their energies in the hope of attaining fame, and yet too often without any success—a sobering warning to modern aspirants for literary honours, that success in gaining immortal fame is unlikely to be attained without hard honest work and ability." The book-lover knew well the advantages of his friends, the dead authors to whom he could turn for counsel and comfort at any time of day or night. Librarians who thus introduced the present to the past should be the friends not only of those whose messages were under their official guardianship, but of those who came to listen and to learn. And so he ended with a reference again to MacAlister, the model librarian, who sacrificed his own ambitions to satisfy those of others in study and publication.

A warm vote of thanks was accorded to Sir Humphry Rolleston on the motion of Major RICHARD RIGG, the chairman of the hospital, seconded by Mr. ERNEST CLARKE, and supported from the chair by Mr. HERBERT J. PATERSON, the president of the society.



AUSTRALIAN INSTITUTE OF ANATOMY.

By a unanimous vote the Federal Parliament of Australia recently authorized the immediate construction, according to revised plans, of an Institute of Anatomy at Canberra, at a cost of approximately £100,000. The Institute will have as its first director Sir W. Colin Mackenzie, M.D., F.R.C.S., whose unique collection of specimens of the native fauna will serve as the basis of a wider collection which is intended to embrace every aspect of anatomy. On his return to Australia after the war he resolved to devote his life and resources to the study and preservation of the "living fossils" of his native land—platypus, echidna, and the many forms of marsupials—all of which were threatened with speedy extinction. Some of our readers will recall[1] that when it was determined to centralize the Commonwealth Government at Canberra a scheme was sanctioned for the erection of a national museum of Australian zoology in the new capital, and that Professor Colin Mackenzie was called upon to organize and direct this great undertaking, which is henceforth to be known as the Australian Institute of Anatomy.

[1] *British Medical Journal*, September 22nd, 1928, p. 539.

The architectural drawing reproduced herewith shows the new Institute as it will appear when completed. The height of the building will be 36 feet, and it will have a frontage of 183 feet, and a depth of 134 feet. It will comprise a block devoted to administration and research, and a museum. The administrative block will consist of a basement; a ground floor, containing the entrance hall, an anthropology room, a department of histology, the director's and secretary's offices, waiting rooms, research rooms, a library, and a lecture theatre seating 200; and a first floor, which will be occupied by a dissection room, a department of osteology, six research rooms, and a room for still and cinematographic projection. The museum block will be made up of two units, each 87 feet by 52 feet, and containing a basement for storage, a ground floor for the exhibition of specimens, and a gallery. The building will be completed in April, 1930.

Besides this provision, an area of 80 acres has been reserved on the River Molonglo, in connexion with the Institute, where it will be possible to study the Australian fauna in their natural state.

Nova et Vetera.

GILBERT MAMINOT, THE CONQUEROR'S PHYSICIAN.

Our knowledge of Gilbert Maminot, Bishop of Lisieux and physician to William the Conqueror, rests principally upon the account of him given by Ordericus Vitalis, in his *Ecclesiastical History of England and Normandy*. Ordericus was a contemporary, and would appear to have known him well. This is what he has to say about him:

"Gislebert, surnamed Maminot, the king's physician and chaplain, was chosen bishop of Lisieux, and consecrated by Michael, bishop of Avranches, in the presence of the lord archbishop John, who, as we have said, had lost the use of his speech. He was a son of Robert de Courbépine, a brave knight; and, filling the see twenty-three years, managed ecclesiastical matters with a strong hand. Though deeply skilled in the art of medicine, after he became bishop he was unable to cure himself. He was eminent for his learning and eloquence, abounded in wealth and the luxuries it procured, but was a slave to his own gratification and the care of the flesh. Ease and leisure were his great objects, and he indulged frequently in dice and other games of hazard. Negligent and slothful in his ecclesiastical duties, he was ready and active enough in hunting and hawking. He therefore devoted his life to worldly exercises and employments, and did not give them up till age compelled him. I could write more about him, but I check my pen, because it was by him that I was admitted to the order of subdeacon, with (as well as I can recollect) three hundred others. But as I have mentioned some things that were not very creditable to him, it is but right that I should record his merits and his doings which are worthy of imitation. He gave alms freely to the poor, and was distinguished for a stately sumptuousness and wise liberality. In his judgements he keenly investigated the truth, and was indefatigable in defending the right, dispensing justice freely to all who came for it. He treated with gentleness offenders who humbly confessed their sins, and judiciously gave wise and salutary counsel to true penitents. He performed the ceremony of conferring sacred orders, and of consecrations, with care and devotion; but he was inert and difficult to be roused to undertake them, nor would he engage in these offices until he was compelled by the united entreaties of numbers. . . . He maintained those appointed to office in the church at Lisieux by bishop Hugh, and gave them instructive lessons in the wide field of arithmetic, astronomy, physics, and other profound sciences, receiving them as his guests, and familiarly conversing with them at his entertainments."

Gilbert was tall and spare; he was addicted to watching the stars, and drew the usual supernatural inferences from anything unusual which he happened to observe.

In the year 1089 Gilbert's disputes with the monks of St. Evroult culminated; he had refused to give his benediction to their abbot unless the latter signed a profession of canonical obedience. This controversy had been going on for ten years, and was finally settled by Gilbert giving way, under royal pressure, in the year above named. Gilbert Maminot died at an advanced age in August, 1101.

Of his patients the only one of whom we have much knowledge is his master, the Conqueror. Gilbert was in attendance during the four weeks which elapsed between William's abdominal injury and his death in 1087. This responsibility he shared with Guntard, abbot of Jumièges. He was present, in his ecclesiastical capacity, at William's funeral at Caen.

Gilbert was made bishop of Lisieux in 1077; he assisted at the Council of Rouen in 1096.

It is unlikely that Gilbert Maminot was much in England at any time, but he was a tenant *in capite* of an estate of twelve hides in Gloucestershire; he had here as subtenant one Hugo Maminot, obviously a relation. It should be noted that this estate was his personal property apart from his position as Bishop of Lisieux. The bishopric owned land in Wilts, Dorset, Hertfordshire, Bucks, and Oxfordshire, as well as two *mansiones* in York. R. R. J.

British Medical Journal.

SATURDAY, JUNE 29TH, 1929.

A NATIONAL MATERNITY SERVICE.

IN an article in our issue of April 13th last (p. 691) Dr. Farquhar Murray well says that "the problems of maternity provide the greatest possible scope for organized preventive medicine. By means of an adequate maternity service many of the deaths and much invalidism resulting from childbirth could be avoided." The problems indicated have been under consideration and discussion by the medical profession and others for a considerable number of years, and there is now a decided feeling among the profession and the public that early and practical steps should be taken to deal with them on a national basis.

The British Medical Association has taken a large part in the effective consideration of these matters, though its activities have perhaps received an insufficiently wide recognition. During the past five years, to go no further back, a considerable part of the time of the Council and of the Representative Body has been occupied with the problems of maternity. In addition to the ordinary work of the Maternity and Child-Welfare Standing Subcommittee, two special committees have dealt with special aspects of the subject. An influential and representative conference was called in January, 1928. Evidence containing definite proposals for the lines of action was given before the Royal Commission on National Health Insurance, and, more recently, before the Departmental Committee on the Training and Employment of Midwives. In the columns of the *Journal*, besides the reports of the committees or conferences and the memorandums of evidence above referred to, there have appeared a large number of articles and letters offering important and suggestive contributions to the discussion. Finally, in this week's *Supplement*, in the Supplementary Report of Council (p. 258), will be found the details of a scheme which is recommended to the Representative Body "as a contribution, on lines acceptable to the profession, towards the establishment of a national maternity service."

It is of some importance to note that during the earlier years of the discussion from which this practical scheme has emerged there was definite diversity of opinion within the profession as to the lines on which a solution was to be sought. One school of thought, probably never having any large number of adherents, but marked by the definite pronouncements of a few very influential persons among those adherents, maintained that safety lay mainly in the direction of a large increase in the institutional provision for both normal and abnormal confinements, and for the setting up, under the auspices of local health authorities, of an extensive service of specialist obstetricians, general practitioners being either wholly excluded from this work or admitted to it only after strict tests of skill and reliability applied by some competent authority, and on an obligation officially to furnish a detailed report of their treatment to some superior officer. It may be useful to refer to a leading article on this aspect of the subject which appeared in the *Journal* of June 12th, 1926 (p. 999); but there have been indications recently that one or two of the advocates of such a system have considerably modified their attitude, and such a solution as that above suggested can now commend itself only to an occasional professor or to a few members of the public health service. The general opinion of the medical profession has developed, more and more strongly, on entirely different lines; and these other lines are also those indicated by the Report of the Royal Commission on National Health Insurance, and by the general body of evidence which has been presented to official or scientific committees of inquiry. It is being recognized with increasing emphasis that ante-natal care and the supervision of childbirth and of the puerperium are the business of the general practitioner, that full and organized co-operation between doctor and midwife is a necessity, and that specialist advice and institutional accommodation must be available for all cases which require them.

It is on these lines that the scheme now put forward by the Council of the Association is constructed. It is avowedly based upon the three principles: "(*a*) that the normal case can be safely treated at home; (*b*) that maternal mortality and morbidity can be very greatly reduced when proper ante-natal care and supervision during confinement is provided in all cases, together with institutional accommodation for cases of complicated labour; (*c*) that maternal morbidity can be greatly reduced with proper post-natal care and treatment." The second of these statements is now accepted almost as a commonplace; the important things to note in connexion with it are that there is great need for the better instruction of the general body of midwives in accurate ante-natal observation, and to some extent of medical practitioners in ante-natal examination, and that, apart from their use as educational centres, and in some areas as convenient places at which practitioners may examine their patients in the presence of the midwife, ante-natal clinics are not necessary to ensure proper ante-natal care. The third of the above statements of principle has been less frequently made but is equally important, as is emphasized by Dr. James Young's article on "The woman damaged by child-bearing" published in the *Journal* of May 18th last (p. 891).

The attention of the profession and of the public should be particularly drawn to the first of the enunciated principles—that the normal maternity case can be safely treated at home. To support this proposition it is not at all necessary to draw any comparisons between statistics relating to institutional and to domiciliary cases; still less to seem to disparage in the slightest degree the excellent work of institutions. It is admitted, however, that the congregation of maternity cases in institutions has certain possible dangers, and that there have been a large number of private practices, conducted over a long series of years and in most unsatisfactory housing conditions, which show a surprisingly low maternal mortality. The statistics given in the Council's report of the outdoor practice of maternity hospitals and institutions may fairly be said definitely to establish the proposition laid down. This is of the first importance, for it allows of a national scheme on the basis of home attendance in confinement, and of institutional provision mainly restricted to those abnormal cases which really require it on medical grounds. Such a scheme, providing for everything that is essential, but not setting out to supply all those things which may be called in this connexion luxuries or mere conveniences, yet leaving a margin, as it does, for the adequate training in normal cases of the midwife and the medical student, is certain to receive a careful and sympathetic consideration from all those who are concerned with the problem towards the solution of

which it is offered as a contribution. Its details of organization, statistics, and finance are of very great interest. It is understood that the Ministry of Health is preparing a scheme with a view to legislative and administrative action. The Association's proposals, along with those which will be shortly forthcoming from the Departmental Committee, will certainly be found of service. They at any rate indicate the lines upon which the medical profession would be willing to offer its zealous co-operation for the national good.

THE INDIAN MEDICAL SERVICE.

DURING recent years the medical services of the armed forces have been passing through a period of stress and difficulty, due primarily perhaps to the reaction against such service following on the experience of the great war and the inevitable difficulties of post-war reorganization, but in part also to the rival attractions of the expanding public health services at home and the increased demands of the colonial medical services overseas. In the case of the Indian Medical Service these factors have been reinforced, not only by the difficulties and uncertainties common to all Indian services in existing political conditions, but by long-drawn-out suspense as to the basis of reorganization of the military medical services in India. Other contributory factors have been the altered status of medicine under the reform scheme as a "transferred" subject administered by Indian provincial ministers, and by the loss to the I.M.S. of a number of minor civil surgeoncies and a few important teaching posts through the formation of a provincial cadre of non-I.M.S. appointments. It is little wonder, then, that during some years recruiting for the I.M.S., more especially of British officers, has been for the most part limited to temporary appointments, when not actually in abeyance.

The publication in 1928 of the reorganization scheme for the medical services in India and the resumption of recruitment for permanent commissions in the I.M.S. did something to improve a position of the utmost gravity. But, apart from the wider issues of the transition period in India, two main sources of dissatisfaction remained which, in the opinion of the Council of the British Medical Association, were in themselves sufficiently important to hinder an adequate supply of European candidates for the Service. The first was that the chief administrative posts under the provincial Governments were omitted in the scheme from the list of appointments reserved for officers of the I.M.S. Secondly, the shortage of recruits so impeded the transfer of officers from military to civil employ as to minimize what has always been recognized as the chief attraction of the Service. As reported in the *Supplement* to our last issue (p. 241), the chairman of the Naval and Military Committee was able to inform the June meeting of the Council of the British Medical Association that steps have actually been taken to remedy both these defects. Further information will be found in the *Supplement* this week (p. 253).

In the first place it has been ruled that, until all officers in civil employ at the date of publication of the reorganization scheme have retired or been otherwise provided for, the chief civil medical administrative posts under the provincial Governments will be filled by officers of the I.M.S. This means on the one hand that the provincial departments will for some twenty-five years enjoy the services of the most competent officers, both British and Indian, likely to be available during that period, and on the other that the legitimate interests not only of the British members of the Service, but also of the pick of the young Indian practitioners, many of whom have incurred the labour and expense of acquiring British qualifications, will be adequately safeguarded. The proviso does not, of course, directly affect future entrants to the Service; it does, however, remove a doubt as to fair dealing with the existing Service, the significance of which at the present time will be recognized by those who are conversant with Indian conditions. In the second place, the end of the block in the transfer of officers from military to civil employ is now in sight. The resumption of recruiting has already eased the position, and the military authorities, realizing the nature of the impasse, have agreed to reduce their demands by no fewer than fifty British officers. This leaves only twenty-two to be recruited as from the beginning of the current year, and of that number sixteen have already been accepted and are under training, while the remaining vacancies, which have already been advertised in the *British Medical Journal* and elsewhere, will doubtless be filled in the course of the ordinary summer recruiting next month. As soon as these officers have received a year's training in India the flow into the civil branch of the Service will be renewed. Full particulars with regard to the conditions of service, pay, and pensions can now be obtained on application to the India Office, and it is perhaps pertinent to observe that candidates entering the Service at the moment will be in a particularly favourable position as regards prospects of promotion, owing to the preceding period of suspended recruiting.

The Council of the British Medical Association heard with great satisfaction that once again its efforts to secure the removal of obstacles to the efficient working of a service in support of which the Association has always been particularly active had been crowned with success. It has informed the India Office that it is now prepared to assist, as heretofore, in obtaining an adequate supply of recruits. Members of the Indian Medical Service will doubtless feel that the presence at the India Office of so distinguished and experienced an officer as Sir Leonard Rogers has not been without its influence in determining the sympathetic attitude of both the civil and military authorities in this matter.

He would be a bold prophet who should venture at this juncture on a definite forecast of the future of any Indian service, but to the tale of obstacles removed we may fairly add some account of definite advances which we understand have already been achieved. The military branch of the Service is now working in harmony with the Royal Army Medical Corps in well-equipped station hospitals. Thirty well-qualified British officers have entered the Indian Medical Service in the course of the past twelve months. The fact that at present junior officers seldom avail themselves of the right to retire with a gratuity of £1,000 after six years' or of £2,500 after twelve years' service seems to indicate that the financial position is not unsatisfactory. As compared with that of twenty or thirty years ago, indeed, it is definitely satisfactory. India is not exempt from the general post-war rise in both costs and standards of living, but the pay, including the overseas allowance, is at three times the old rate, while the sterling value of the rupee is nearly 50 per cent. above the rate then prevailing. Passages are now available for

officers and their families going on leave, provision is made for study leave, and freedom from moves during the first year's service is guaranteed.

There remains one feature of the position the importance of which for the future of India and the I.M.S. can hardly be exaggerated. The development of the research department, so far from being checked by recent difficulties, has received a definite impetus during the past few months. The scheme described in the *British Medical Journal* for December 1st, 1928 (p. 1001), has been accepted, including a new central research laboratory with twenty acres of ground in the favourite station of Dehra Dun and a new public health laboratory opposite the Calcutta School of Tropical Medicine. This last, made possible by the generosity of the Rockefeller Foundation, will also be maintained and staffed by the Government of India. An officer of the I.M.S. has just been appointed as its first head, and members of the Service will be eligible for such posts in the future. If such development continues unchecked (and it must be remembered that research, as a "reserved" and not a "transferred" subject, has some slight protection against the changes and chances of the transition period), the I.M.S. should offer to selected workers, both British and Indian, an entrance to a field of research unrivalled in any part of the Empire.

MEDICAL EDUCATION.

THE problems of medical education are not only many and difficult; they are to a considerable extent contradictory. The demand for a somewhat later beginning and for a simplified and, if possible, shortened curriculum is combined with the suggestion that many parts of the curriculum should receive fuller attention, and that further subjects—some purely professional, others not strictly medical, but having a useful if not essential value in relation to medical practice—should be added thereto. The nature and cost of medical education are, of course, of interest not merely to actual and prospective members of the profession itself, but also to the public in general, for on the efficiency of such education the safety of that public in health matters depends, and on the cost of such education depends in large part the cost to the public of its medical care.

We are reminded of these things by a paper recently read before the Annual Congress on Medical Education, Medical Licensure, and Hospitals, Chicago, by Dr. Ray L. Wilbur.[1] The conditions in this regard in the United States are not quite the same as with us, but similar problems arise and similar principles are applicable. The relative efficiency of medical education in America is of more recent establishment than here. As Dr. Wilbur says: "A generation ago we were well behind the schools of Europe, and the aim of an ambitious student was to round off his training *in a foreign clinic.*" As a reaction from this there is, he thinks, now "some distortion of the whole scheme of medical education," and "there is developing an exuberance in some plans for buildings for medical instruction In one great city the plan is going forward for the construction of a plant at an approximate cost of 55,000,000 dollars, with the primary aim of undergraduate instruction of medical students. With a striking absence of facilities for post-graduate training it seems absurd to aggregate such large sums of money in metropolitan centres for undergraduate medical instruction. *No such sums are actually required to* give the training necessary." We can the more readily agree with Dr. Wilbur, inasmuch as we are not likely to be faced in Great Britain with any financial proposals of such magnitude, and believe that we can maintain a satisfactory position without them. Here, as well as there, however, in Dr. Wilbur's words, "It is important that a proper scheme be evolved so *that medical education may not put too great a cost* on the sick. We do not want cheap education or cheap men; but we do need to demand all the economies that are reasonable and possible during the period of medical training if we are to solve the problem of the distribution of medical service at a reasonable cost to the public." Dr. Wilbur demands not only simplification of plant, but a shortening of the period of medical study, while at the same time he suggests that training in the field of economics and social organization should be added to the course. He *does not succeed in showing exactly how this is to* be done.

The whole field needs to be surveyed from time to time in its due perspective, and not the less now because the General Medical Council has in some sort made such a survey of existing conditions. The main points to be determined are (1) what it is that we are to expect of the medical student at the time of his qualification; (2) how far we are to rely on preliminary and pre-medical education to enable the required result to be produced, and on post-graduate opportunities for further progress; and (3) how best the intervening undergraduate medical course can be arranged and utilized. On the first point we have previously said in a leading article in this *Journal*:[2] "There is no pretence that a medical student, on passing his qualifying examination, has become a wise practitioner or is specially skilled in any branch of his profession; but his training and knowledge should even then be such that he can safely undertake many kinds of medical and surgical work, that after relatively short further experience he can properly assume considerable responsibility in one or other of the local government medical services, and that he will be in a position fully to profit by increasing experience, whether in such service or in private practice." On the second point we have raised the question whether the time is not now ripe to raise to 18 years the age at which medical education, properly so called, should begin, and as to whether prior to this commencement there should not be required evidence, not merely of a good general education and of some knowledge of physics and chemistry, but of a thorough grounding in these basic sciences, and especially in organic chemistry and in biology, so that throughout the medical curriculum proper it would be only the medical and surgical applications of these sciences that would be taught. On the third point we have emphasized the advantages of the British plan of picking up clinical methods and pathology while in daily contact with patients, rather than that of assuming that the ideal medical man can be rapidly made out of a well-drilled laboratory pupil. There is nevertheless need—and Dr. Wilbur has performed a real service in pointing this out—for reasonable opportunity for the medical student acquiring some knowledge of economic and social sciences, and, we would add, of psychology also. Perhaps such opportunity would be sufficiently provided if undergraduate medical education were pursued always under true university conditions rather than in the narrower atmosphere of an isolated medical school.

ENCEPHALITIS LETHARGICA IN CHINA.

REFERENCES in the literature to the existence of encephalitis lethargica in the Far East are increasing, and the latest contribution to knowledge of the disease in China is supplied by Dr. Maximilian Pfister, whose article we publish on page 1156 of our present issue. With the special opportunities afforded by his position as neurologist at the Peking Union Medical College the author has been able to study the disease in 100 patients coming under his observation during part (2½ years) of the period 1923–25. Of this series—the largest so far reported from China—more than half the number of patients came from Peking and its neighbourhood, and the remainder from coastal towns in China. As in this country, the disease was most prevalent during the cold season, it affected those of sedentary occupation rather than outdoor workers, and its chief incidence was among those between puberty and middle age; as regards sex incidence, however, it is interesting to note that 80 per cent. of the patients were males. The clinical picture is also said to be similar to that presented by European patients, and in this series of cases, as in many others, Parkinsonism was the commonest form of post-encephalitis. It is noteworthy that Dr. Pfister refers to the occurrence of epidemic outbreaks in the neighbourhood of Peking and in particular to "a small epidemic of benign character," which occurred during 1924, the peak year in this country, when the disease, though unusually prevalent, was comparatively mild in character; during the same winter the author met with abortive forms of the disease. Regarding the presence of encephalitis lethargica in China, Dr. Pfister considers that the disease has been imported from the West along the sea routes from Europe and by way of India to the ports of China; as Dr. Pfister says, this would certainly appear to be the most likely route by which the infection of cosmopolitan diseases would reach China. Dr. Pfister makes the additional suggestion that the infection of encephalitis lethargica was originally brought to China from Europe by Indo-Chinese troops returning from the European war areas. On the other hand, Dr. A. J. Watson of Yunnanfu, in a paper which received notice in our issue of August 18th, 1928, and to which Dr. Pfister now directs critical attention, puts forward the hypothesis that the infection of encephalitis lethargica was taken out of China by those Chinese who took part in the European war and by them disseminated among the combatants of other nations. Dr. Watson's hypothesis rests particularly upon the assumption that one of the 19 patients seen by him during 1928 was correct in referring the onset of his illness to the year 1915 and upon the inference that there may have been other undiscovered cases in China about, or even before, that time. Dr. Watson was impressed by the fact that most of the patients seen by him came from remote country districts which they had not previously left, and where, in normal times, the inhabitants have little intercourse outside their own villages; in this comparatively isolated province of Yunnan encephalitis lethargica is considered, indeed, by Dr. Watson to be an endemic disease. Dr. H. P. Yew has more recently[1] expressed a similar belief, based upon an experience of thirty odd cases seen over a period of two years in Yunnan Province. Dr. Pfister, however, questions the reliability of the case-history given by this particular patient of Dr. Watson, despite the belief of both Dr. Watson and Dr. Yew that the evidence was trustworthy. He also assails the argument used by Dr. Watson in support of his notion that the disease may have originated in Yunnan Province. The fact, adduced by Dr. Pfister, that troops from Annam were engaged at Verdun and returned from that front in 1915 rather supports the supposition that the disease was introduced into China from France, but at the same time it is not altogether irreconcilable with Dr. Watson's hypothesis. The world war certainly provided a unique occasion for the dispersion of diseases which may have been previously localized; and, speaking generally, there does not seem to be anything too far-fetched in the idea that through the intermingling of soldiers, many of them recruited from remote districts in their own countries, a specific infection might be released—so to speak—and be carried for the first time out of a country, such as Yunnan, where its activities had previously remained endemic and beyond the ken of trained observers. There is still a good deal that is obscure about the early history of encephalitis lethargica. Its primary appearance (or possibly reappearance) in epidemic form can clearly be correlated with the outbreak of the great war, but recent references to its antecedents would seem to suggest that its irruptions in various countries were more nearly coincident in point of time than the early successive series of published case reports might lead one to suppose. It is to be hoped, therefore, that, while clinical witnesses may yet be available, other medical observers in China will be stimulated to co-operate in the interesting investigation initiated by Dr. Watson and Dr. Pfister.

THE LISTER INSTITUTE.

THE annual general meeting of the Lister Institute of Preventive Medicine was held on June 19th, when the governing body presented its thirty-fifth annual report to the members. Before proceeding to give a brief survey of the researches in progress during the year in the various departments of the Institute, the report makes acknowledgement of the continued co-operation given by the Medical Research Council, the Department for Scientific and Industrial Research, the British Empire Cancer Campaign, and the International Committee for the Study of Infantile Paralysis. Grants from these bodies to skilled investigators have added greatly to the range of scientific work carried out at the Institute. We can only mention here a very few of the multifarious activities of the year under review. Professor J. C. G. Ledingham, working with Dr. McClean in the bacteriological department, has published experiments showing the possibility of propagating vaccine virus from dermis to dermis of the rabbit by intracutaneous inoculation. In the course of such passage the virus appears to acquire a greatly increased capacity for proliferation in the dermis, and a corresponding diminished capacity for proliferation in the shaved skin. In collaboration with Dr. Mary Barratt, Professor Ledingham has been investigating certain problems concerned with the generalization of the lesions of vaccinia; he has also studied the "elementary bodies" (0.2μ in diameter) in vaccine virus first described by Paschen in 1906. A systematic study of the vaccine virus *in vitro* is being carried out by Drs. Eagles and McClean; their observations throw doubt on the generally accepted view that actively growing cells are necessary to the propagation of the virus. A considerable amount of research on poliomyelitis has been undertaken, the cost being defrayed by a grant from Mr. Milbank of New York. Reinvestigation of the histology of the experimental disease in monkeys indicates that the nerve cell destruction is to be regarded as a primary event, and not due to the interstitial changes. An inquiry into the part attributed to cocci in the etiology of experimental poliomyelitis has ruled out such micro-organisms as causal factors. Attempts to reproduce the disease in rabbits have failed. Investigations bearing on the vitamin content of various Empire products are being carried out by Dr. S. S. Zilva and his colleagues in the department of biochemistry; the expenses of these are defrayed by a

grant to the Medical Research Council from the Empire Marketing Board. The work undertaken in the departments of chemistry and of experimental pathology has included researches on the anti-scorbutic principle (vitamin C) and the metabolism of animals affected by scurvy; and also a large number of experiments in nutrition bearing upon the properties and distribution of water-soluble B vitamins in natural foodstuffs, and the occurrence and nature of vitamin A. In order to fill a blank in our knowledge of the biological action of light Sir Charles Martin has tried to determine what proportion of the total radiant energy of sunlight is absorbed by the skin and various fabrics and converted into heat. Absorption by the skin varied from 65 per cent. in the very fair complexioned to 87 per cent. in the negro. Dr. Korenchevsky's work on the endocrine glands has included attempts to obtain a specifically active extract from the testicle and prostate, but so far without success. Dr. Lumsden has continued his researches on cancer; after many failures results are now being obtained which promise some success in preventive vaccination against implanted tumours. During the year the national collection of type cultures has grown, over 300 new strains having been added, and 5,000 cultures distributed. In this department many useful investigations are constantly being carried out for the identification of strains on behalf of biologists who do not possess equipment and conveniences for such work. In conclusion, the report notes that a self-contained laboratory and two bungalows, with six acres of land, at the Serum Department, Elstree, have been rented to the Cancer Hospital for investigations by members of the staff of the research institute of that hospital.

CAVERNOUS SINUS THROMBOSIS.

THE paper on cavernous sinus thrombosis by Dr. E. A. Scale of Grahamstown, South Africa, which appears elsewhere in this issue (p. 1155) gives details of the recovery of one of that type of case, which is so desperate that mercifully it is equally rare. That it should be so rare is a matter of some wonder, considering the anatomical relation of these venous sinuses in the basis cranii. The cavernous sinuses lie in a relatively thin-walled sulcus of the floor of the skull, in bone which forms the roof of one of the air sinuses; this air sinus communicates with the "rabbit warren" of the nasal sinuses, and it is but little removed from the roof of the pharynx. The frequency of nasal infections makes the escape of the venous sinuses remarkable. Again, the sinuses themselves are like under-street tunnels for the number of vessels and nerves that run within the dural sheath of the sinuses and actually bulge into the passage ways. Where there are so many and such close possibilities of inflammatory reactions from contiguity, or of infections that have spread to the sinuses themselves, the rarity of thrombosis is amazing. The clinical symptoms of the disease are unmistakable. The sudden and severe proptosis of the eye, the protuberant lids and conjunctiva, and some degree of optic neuritis—all point clearly to the diagnosis of a retro-bulbar affection of great severity. And if the actual nature of the diagnosis should still be in abeyance for a few hours, it is soon settled by the appearance of the same symptoms in the other eye. Treatment is almost hopeless. All that can be done is thoroughly to open every nasal air sinus that may possibly be the seat of the primary infection, and drain them well. But unfortunately the patients are usually so ill that the surgeon may deem operative measures of any extent almost unjustifiable, even though they present the last chance; yet the patient should be given this last chance. In the few cases in which recovery has been recorded there has been permanent disability, blindness to a greater or lesser degree, and facial deformity owing to exophthalmos. The occurrence of such cases as these points to the urgency of evacuating discharges from septic air sinuses in and behind the nose, and of securing free drainage. No one doubts the urgency of such measures in mastoid disease; it is no less urgent in sinus disease. Dr. Scale is to be congratulated upon the successful treatment of his patient, and upon the fact that there was such a good measure of recovery that the woman was able to earn her living once more as a laundress. He modestly attributes her recovery to the high resisting powers of the negro.

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.

THE annual report on the museum of the Royal College of Surgeons of England issued by the conservator, Sir Arthur Keith, includes the reports of the curators of the several departments, together with a general survey of the year's work by the conservator. In the latter special mention is made of those who have contributed specimens to the museum during the year, and it is satisfactory to find that so large a number of medical men, not officially connected with the museum, take an interest and pride in it. On the pathological side the curator, Mr. C. F. Beadles, F.R.C.S., reports the addition of over a hundred and fifty new specimens; these, with the additions to other departments, will be on view in Room I of the museum from July 4th to July 27th. Special mention is made by the curator of the numerous additions to the brain and nerve series and to those of the thyroid and pituitary glands. There are also some beautiful preparations illustrating von Recklinghausen's disease, which by themselves are well worth a visit to the museum; and many individual specimens of conditions of which the opportunities for study are infrequent, such as the results of bone grafting for tuberculous disease of the spine, osteoporosis of the skull from diet deficiency, a condition resembling leontiasis of the cranium following injury, and mediastinal teratoma. A comparatively new department is that of palaeopathology, dealing with prehistoric diseases. This is a subject in which Sir Arthur Keith takes a special interest; he has already secured the aid of many possible donors in various parts of the country, and in this way has accumulated a nucleus for a section of British palaeopathology. A notable contribution to this section is due to Dr. Wingrave of Lyme Regis, who has presented a number of specimens of fossil vertebrae of the extinct reptilia; these represent the earliest traces of disease which have so far come under the eye of the geologist. In the department of human osteology Miss Tildesley has made progress in the cataloguing of the collection of human crania. When this work is completed the collection will form a valuable standard of reference in determining the racial affinities of excavated human remains. Many interesting specimens have been added in the physiological department; among these may be mentioned a series of dissections of brains of the higher primates, showing the relative development of the basal ganglia in relation to the expanse of the cortex. From these dissections it appears that in the human brain the basal ganglia have undergone as great a progressive expansion as the cortex. The curator of this department, Mr. R. H. Burne, F.R.S., has continued his investigations on the component of the vascular system of bony fishes, which was discovered by him; and several researches of interest have been carried out by other investigators. Under the care of its honorary curator, Sir Frank Colyer, the odontological section is now one of the most pro- gressive and rapidly expanding parts of the muse every effort is evidently being made by him to re the collection representative in every detail. historical department Mr. C. J. S. Thompson

honorary curator, is able to report the addition of a large number of surgical instruments, most of them presented by that indefatigable antiquarian Dr. F. W. Cock.

BILHARZIASIS IN PALESTINE.

DR. H. GOLDIE, medical superintendent of the "Hadassa" dispensary at Tiberias in Palestine, has prepared a useful report[1] on bilharziasis in Palestine. His cases fall into two groups. The first and most numerous were all acute cases, among males aged 17 to 32, infected in Egypt or in Palestine, in the Auja district. These patients usually complained of symptoms of cystitis, and always had albumin and blood cells in the urine; the ova of bilharzia were not found on every occasion; two patients had been hastily diagnosed elsewhere, without careful examination, as cases of chronic gonorrhoea, but ova were found in their urines, and, as in the other cases, they were cured with intravenous tartrated antimony, which these patients take very well. In the second and more interesting group of 28 cases the nature of the illness was revealed by the routine urine analysis which is made for all patients of the dispensary; the patients did not complain of urinary symptoms, but of anaemia, dysmenorrhoea, and lumbar or abdominal pain, while three were found to have pneumonia. Ova were present in all the urines, with blood cells, and most patients had albuminuria, which was generally slight. All the 28 were Jewish immigrants from Arbela in Mesopotamia, their ages ranging from 10 to 60; 26 of them were female and only 2 were men, and they had been in Palestine from two to nine years. The whole of this colony, 82 persons in all, was examined; 28 patients had the characteristic ova, 16 only cells, and the rest were apparently well. The men were shopkeepers or craftsmen; the high infection rate of the women was explained by the fact that at Arbela they had had to wade out twice a day into the stream to fill their water jars. They had not set up an endemic focus of the disease in Palestine, for there are no Bulinus snails about Tiberias. This group of enfeebled people reacted badly to tartrated antimony, which gave rise to unpleasant cough or giddiness. Other preparations were tried, therefore, and Dr. Goldie was most successful with antimosan in intramuscular injection, which was usually painless. He began with 2.5 c.cm. of a 5 per cent. solution; after the dose of 40 c.cm. the ova generally disappeared, but the proof of the death of the parasite—absence of the ova from the urine three months later—was only expected if treatment had continued until 65–70 c.cm. had been administered.

PASTEUR'S EARLY WORK ON THE NATURE OF INFECTIVE DISEASE.

THE beautiful edition of Pasteur's works which is being issued by Masson et Cie under the editorship of Professor Pasteur Vallery-Radot, and is to be completed in seven volumes, should find a place in every medical library. The fourth volume, containing the studies on silkworm disease, has been referred to already in this *Journal* (March 5th, 1927, p. 436). The fifth volume,[2] recently issued, contains the work published in 1876 under the title "Studies in beer, its diseases, the causes which produce them, and the method of rendering it stable; with a new theory of fermentation." The famous researches described in this volume foreshadowed in the clearest manner a true and scientific comprehension of the nature of infective disease, at a time when the prevailing doctrine was that disease arose "in us, from us, and by us." Pasteur clearly foresaw the approaching revolution of ideas on this subject; "it is possible," he writes in his preface, "that an unexpected light is about to be thrown on the causation of contagious disease." He showed how the normal alcoholic fermentation of beer might be deranged owing to its accidental association with other forms of fermentation, each with its specific organism and each producing definite symptoms or signs in the form of "turning," viscosity, putridity, or acetic or lactic acidity. "From the physiological point of view all these ferments are equivalent. The botanist and savant, students of nature, give equal attention to plants, whether they are useful or hurtful, because they are subject to the same natural laws; but industry and hygiene have other standpoints." Analogous phenomena occurring in man and animals would be regarded as diseases. The suggested analogy proved to be sound, and the important principle of specificity in bacterial disease became securely established on a scientific basis. A recrudescence of the theory of spontaneous generation, chiefly through the influence of Bastian, acted at the time as a slight obstacle to the general acceptance of Pasteur's views, but the theory received its final quietus at the hands of Tyndall, a letter from whom, referring to this subject and to Pasteur's work generally, is included in the present volume. "For the first time in the history of the science," he writes, "we have the sure and certain hope that, in regard to epidemic diseases, medicine will shortly be delivered from empiricism and placed on a genuine scientific basis; when this great day arrives, humanity, in my opinion, will remember that its gratitude is due principally to you."

VICTOR HORSLEY LECTURE.

THE third Victor Horsley Memorial Lecture will be delivered by Sir Thomas Lewis, M.D., LL.D., F.R.S., Physician to University College Hospital, who has taken as his subject "Observations relating to the mechanism of Raynaud's disease." The lecture will be given at University College Hospital Medical School, Gower Street, W.C., on Tuesday, July 16th, at 5 p.m., under the chairmanship of Sir John Rose Bradford, K.C.M.G., M.D., F.R.S., President of the Royal College of Physicians of London. Admission to the lecture is free on presentation of visiting card.

THE Metropolitan Asylums Board had before it on June 22nd a statement prepared by the medical superintendent of the small-pox hospitals showing the condition as to vaccination of patients suffering from small-pox admitted from January 1st, 1928, to May 31st, 1929. The statement showed that out of 1,057 cases admitted 163 were said to have been vaccinated in infancy only, that the youngest of these 163 cases was 15 years 11 months old, and the evidence of vaccination was doubtful, and that the next youngest cases were 19 years old. Eleven cases were stated to have been vaccinated and revaccinated, but in 7 of these cases the evidence of revaccination was either not present or was doubtful. In the remaining 883 cases there was no evidence of vaccination prior to infection.

ON Thursday, July 18th, the Prince of Wales will open the new building of the London School of Hygiene and Tropical Medicine which has been erected, as a gift of the Rockefeller Foundation, in Keppel Street, W.C. The foundation stone was laid by Mr. Neville Chamberlain, as Minister of Health, on July 7th, 1926.

THE British Orthopaedic Association and the American Orthopaedic Association will hold a joint meeting in London on Thursday, Friday, and Saturday, July 4th, 5th, and 6th.

ENGLISH HOSPITAL PLANNING.

On May 27th Mr. H. PERCY ADAMS, F.R.I.B.A., delivered a lecture on English hospital planning, before the Royal Institute of British Architects. After some introductory remarks, Mr. Adams said that the ideal hospital site was high ground sloping gently from north to south or south-east, and sheltered by trees on rising ground. It should be away from noise and dirt, have good roads on the northern side, a sub-soil of chalk, rock, or gravel, and adequate facilities for water, gas, and drainage. Possibly, in future all large hospitals would be outside the town areas, and only central clearing stations for casualties and out-patient departments in the large towns themselves.

Lay-out of the Buildings.

The various hospital departments, said Mr. Adams, should be arranged in blocks, each in the position most suitable for its individual requirements and in relation to the others, and affording scope for future extension. The administration block should be central, with a main corridor running east and west; the wards should be at right angles, running north and south with cross-ventilation, the out-patient and casualty departments easily accessible from the street, and the dispensary and electrical departments available for both in- and out-patients. The kitchens should be accessible for tradesmen, and centrally placed for serving patients and staff; the nurses' home should be away from, but easily accessible to, the hospital. The boiler-house should be at a low level, and as central as possible, and the chimney shaft away from the prevailing wind.

The Wards.

Mr. Adams drew attention to the recent tendency to reduce the size of the general wards and to have in each unit side wards for special cases. A width of 22 ft. seemed sufficient for a general ward of 16 beds, if it was not used for clinical teaching. The head space for each bed should be not less than 8 ft. from centre to centre, rather more than this for maternity and special cases and a little less for children. Recently many doctors had advocated the plan of placing the beds parallel to the windows. For the new hospital at Southend Mr. Adams was proposing T-shaped wards, containing 24 beds, in sections of 4, 4, and 16, with the beds parallel to the windows, and, to facilitate supervision, having the upper parts of the screens against the heads of beds made of clear plate-glass. The system most generally adopted for heating the wards was by means of radiators under the windows. Heated pipes round the walls, however, were cheaper than radiators, no more difficult to clean, and they gave an equable temperature; they presented, perhaps, a larger surface for the accumulation of dust. The open-air chapel at the King Edward Sanatorium was warmed by means of pipes under the stone-flagged floor. After describing in detail the structure of the general ward, of its doors, windows, and floor, Mr. Adams said that during the past few years the sanitary adjuncts of the ward had been placed near its entrance in order to be under better control, to simplify the plumbing, heating, and drainage, and to be available for the side wards; a ventilated lobby between the sanitary adjuncts of the ward was an advantage.

The w.c.'s should be at least 5 ft. by 2 ft. 9 in., and their doors should always open outwards. The sink room should be at least 10 ft. by 8 ft., with a sink for cleaning bed-pans and urine bottles. An open-air balcony should be provided for refuse bins, and a lavatory for patients; the bathroom should have an area of at least 9 ft. by 8 ft., with the head of the bath facing the window, and its side at least 2 ft. from the wall. In connexion with the wards, Mr. Adams said there should be a ward kitchen not less than 16 ft. by 14 ft., a small, well-ventilated larder, a clinical room, a small sterilizing room in surgical units, a record room for the use of the registrar, a linen store, a patients' storeroom containing numbered lockers, a storeroom for bedrests, splints, etc., a service room for the cleaners' brooms and pails, a nurses' w.c., a day room, a class room, and possibly a sisters' room. It was an advantage to have a balcony at the south end, partly enclosed on the east and west sides.

Wards for paying patients should have easy access to the special departments of the hospital and to the general kitchen, which might be provided with a section where special foods could be prepared. The wards should be supplied with lavatory basins and fitted with wardrobes.

The Operating Theatres.

The most satisfactory provision for students witnessing operations, said Mr. Adams, was a raised platform at the north end of the theatre, having a separate access from outside the theatre. It was an advantage to concentrate the general operating theatres in one block rather than to have them dotted about the hospital. The department should be separated from the main corridor by a ventilated lobby, and should be in a quiet position and not overlooked. The usual plan was to have the theatres with due-north light and the entrance at the south; on one side there should be a room for cleaning the bowls, instruments, etc., and on the other a room for the sterilizers. Adjacent to the theatre there should be an anaesthetizing room, a room for surgeons to change in, a sisters' room, and an instrument room. In large hospitals there were usually special theatres for the ophthalmic, maternity, and casualty departments, and often in the children's block theatres for tonsils and adenoid cases. Mr. Adams suggested that the dimensions of a theatre should be not less than 22 ft. long by 18 ft. wide by 14 ft. high, with a vertical north window 12 ft. wide, and, among other practical details, mentioned the need for setting the glass in frames with rounded corners, an outside balcony giving cleaners access to the windows, provision for cooling the theatre in hot weather, and the desirability of building instrument cabinets into the walls of the theatre with flush, clear glass doors. The flush panel radiator was excellent for heating purposes, and it was advisable to have some of the radiators heated from the general hot-water system, supplementing them with radiators heated by the steam supply, which was always available for sterilizers and cooking. In cities it might be an advantage to use the plenum system of heating and ventilation, so that the air could be well filtered and its temperature regulated before being delivered into the theatre. The doors of the theatre and anaesthetizing rooms should be at least 4 ft. wide and perfectly flush on both sides. For lighting the table the new scialytic shadowless lamp seemed to be in favour. Mr. Adams described also the structure and equipment of the washing-up room, the sterilizing room, and the anaesthetic room.

Electrical Department.

This department, he said, was most conveniently placed on the ground floor, not in the basement; it was essential to place the high-tension generating plant in a room by itself, next to the *x*-ray room, and if there were separate rooms for therapy and diagnosis the transformer room should be placed between them and the door fitted with a switch, so as automatically to cut off the current when the door was opened. The ceilings of *x*-ray rooms should be arranged for suspending the overhead high-tension gear in connexion with the apparatus. Access to the dark room should be either by a revolving light lock door or by a maze light lock without door or even curtain. There should also be a film-filling room, a room for the viewing cabinet, a general storeroom, doctors' and nurses' rooms, and waiting rooms and dressing rooms for patients. For the protection of operators walls were built of bricks made of barium sulphate, or covered with barium plaster or lead, and doors were sheathed with lead. The protection for 100,000 volts was 1.5 mm. of lead, and for 200,000 volts 4 mm. of lead. The thickness of bricks and ordinary concrete that would give protection equal to 1.5 mm. of lead was approximately 5 inches. To protect the dark room and storeroom from accidental exposure the walls should be covered with lead 1 mm. thick. Artificial ventilation was required, and could be supplied by a centrifugal exhaust fan with fresh air (light-protected) inlets.

Venereal Diseases Department.

In planning this department the first principle was to secure privacy for patients and facilities for quick service to the staff. Essentials were a clerk's room next to the consulting room, a patients' waiting room with lavatory accommodation, a general service room for routine clinical pathology, and a

series of cubicles entered by the patients direct from a corridor or waiting room and planned to secure privacy. All the rooms should have the floors and walls of impervious materials and easily cleaned.

Prevention of Noise.

Having described in some detail the architecture of the casualty department, the post-mortem room, laboratories, and the administrative blocks, Mr. Adams said that to guard against noise corridor floors should be insulated, a good method being to have a margin of hard material like terrazzo, with the centre slightly sunk to take the rubber cemented down to it. Lift gear should be placed in insulated rooms and pumps for heating mains connected with flexible rubber. At the entrance to the duct for the main from the boiler-house a felt curtain would help to deaden sound. Self-closing doors with air-pump springs were a great boon for all wards.

POST-VACCINAL ENCEPHALITIS.

NEWSPAPER reports of recent inquests in the London area have reawakened interest in the occurrence of acute disease of the central nervous system after primary vaccination.

The pathology of encephalo-myelitis arising in the course of virus disease and the exanthemata was discussed in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association in Cardiff last year; we reported the proceedings in the *Journal* of August 4th, 1928 (p. 202), and the introductory papers by Professors H. M. Turnbull and James McIntosh appeared in our issue of August 25th (pp. 331 and 334). The debate at Cardiff, on July 25th, turned largely on the question of post-vaccinal encephalitis, and in the same week the report of the Committee on Vaccination, presided over by Sir Humphry Rolleston, was presented to Parliament by the Minister of Health.[1] A considerable part of the Rolleston Committee's report was devoted to diseases of the central nervous system following vaccination, and it included the full text of the report by an earlier committee which went into this subject, under the chairmanship of Sir Frederick Andrewes, between November, 1923, and May, 1925. An account of the findings of both committees appeared in our issue of August 11th (p. 265).

The Andrewes Committee Report.

The members of the Andrewes Committee (Professor McIntosh dissenting) came to the conclusion that it was extremely improbable that the 62 reported cases of post-vaccinal encephalitis in this country could have been due solely to the vaccine virus. On the other hand, they held it not altogether improbable that vaccination might here and there have precipitated encephalitis in a person harbouring another virus. It seemed to them conceivable that "a virus, such as that of poliomyelitis, which can only occasionally set up an encephalitis in a normally resistant person when unaided may, if another virus, such as that of vaccinia, is present in the brain, be enabled to do so." The provisional opinion they reached was that the nervous sequelae under consideration were most satisfactorily explained on the assumption that the vaccine virus had stimulated to activity some latent neurotropic virus harboured by the vaccinated subject, and that to such a combination of viruses might be attributed any notable peculiarities in clinical course, histological picture, and generally lethal character of the cases.

The Rolleston Committee Report.

The Rolleston Committee, which investigated a further series of 25 cases, went very fully into the various theories that had been put forward in explanation of the occurrence of post-vaccinal encephalitis. While it acquitted the vaccine virus of being the *sole* cause of the disease it was unable to exonerate vaccination from playing some part in its causation. Its considered opinion was that the co-operation of vaccinia with the viruses of poliomyelitis, encephalitis, or some unknown neurotropic virus, must be accepted as a working hypothesis of causation, pending further research into the nature and properties of neurotropic viruses in general. This opinion is shared by the Commission on Small-pox and Vaccination of the League of Nations, which reported subsequent to the publication of the Rolleston report. The Rolleston Committee pointed out the extreme rarity of post-vaccinal nervous disease, particularly after revaccination and after primary vaccination in early infancy, from which it followed that early infancy must continue to be regarded as the time of choice for primary vaccination. In order to encourage vaccination the Committee recommended that the customary four insertions of vaccine should be replaced by one, made with a minimum of trauma, and that multiple scarification and (or) cross-hatching should be deprecated. Vaccination in multiple insertions should, however, be available for such persons as desire to obtain the maximum protection against small-pox obtainable at one operation.

The Geneva Memorandum.

The risk of post-vaccinal encephalitis has been discussed also in a memorandum issued last autumn by the Commission on Small-pox and Vaccination of the Health Organization of the League of Nations at Geneva, to which reference was made in our issue of September 29th, 1928 (p. 582). The Commission emphasized the fact that post-vaccinal did not necessarily imply propter-vaccinal; that in view of the millions of vaccinations carried out in any given year there must always be present in the community very large numbers of people subject to the ordinary chances of life, and only incidentally under the influence of the vaccinia virus. Such people were no more immune from disease of the brain and nervous system than anyone else, and there was therefore no reason why the coincidence of vaccinia with a true encephalitis should not be expected to occur. Encephalitis, moreover, occurred as a complication of numerous infections—for example, measles and various forms of toxaemia—and in so far as vaccinia was an infection it might be considered legitimate to regard the cases under consideration merely as instances of ordinary post-infective encephalitis. The Commission, however, was of opinion that there were practical reasons for considering post-vaccinal encephalitis as a separate pathological and clinical entity. Its general conclusion was that the virus of vaccinia could not of itself be considered responsible for encephalitis. It considered rather that some unknown factor—perhaps a filter-passing virus or a latent virus—determined the occurrence of the complication in question.

The age distribution in the incidence of post-vaccinal encephalitis is of particular interest; the bulk of the cases have occurred in children between the ages of 3 and 12. Moreover, the disease follows revaccination of older children and of adults with the utmost rarity, a fact which, taken in conjunction with the almost complete immunity of the first two years, provides ample reason for emphasizing the value of undertaking primary prophylactic vaccination against small-pox as early as possible in life.

Summary.

The rare occurrence of post-vaccinal encephalitis is no reason for lightly estimating its importance; the risk, though small, is of a very dangerous disease. It is necessary, however, to remember that vaccination is not believed to be its sole cause, nor is there any evidence of its transmission by vaccine lymph, however manufactured. In view of the fact that the majority of recorded cases have occurred in persons primarily vaccinated after infancy, it is desirable to advocate more strongly than ever the need for carrying out primary vaccination of infants between the ages of 2 and 6 months. Continued protection against small-pox could then be ensured by revaccination when the child first enters school, and again when he reaches school-leaving age. To avoid undue reaction it would be well to carry out vaccination in one or two insertions, each made with a single linear incision, rather than in the customary four.

Scotland.

Honorary Graduates of Glasgow University.

DR. CHARLES OLIVER HAWTHORNE, F.R.C.P., chairman of the Representative Body of the British Medical Association, was one of a notable group of honorary graduands at the graduation ceremony at Glasgow University on June 12th. In presenting Dr. Hawthorne for the honorary degree of Doctor of Laws (LL.D.), the Dean of the Faculty of Law (Professor T. C. Wright) said that he was a distinguished student and prizeman of the University, where he had graduated with honours. For over a decade he was a much appreciated teacher in the Western Infirmary. Thereafter he transferred his energies to London and became one of the inaugurators of the Polyclinic, the first real post-graduate institution in that city. Gifted with a brilliant and a fearless mind, his trenchant pen was always at the service of common sense and justice in medicine. In addition to his strictly professional duties, Dr. Hawthorne had taken an active part in the affairs of the British Medical Association. In recognition of his services to medical science the Senate desired that there should be added to his Doctorate of Medicine the further degree of Doctor of Laws. At a luncheon held after the graduation ceremony, Sir Donald MacAlister, Bt., principal of the University, in proposing the toast of "The Honorary Graduates," said of Dr. Hawthorne that they greeted him as one of their many alumni, who, having taken high honours in their own schools, had gone forth to seek and find fame in the wider world of London. They now acclaimed him Doctor of Laws in recognition of his success as a medical statesman and organizer. By fearless speech and pointed pen he had won for himself a leading place in the councils of his profession, and he now directed the Representative Body of the widely influential British Medical Association with vigour and sagacity.

Among others who received the honorary degree of LL.D. on this occasion were Sir John Cargill, Professor Carslaw of Sydney, Madame Curie, the Earl of Elgin, Provost Gwynn of Trinity College, Dublin, Herr Fritz Kreisler, Lord Lugard, Lord Provost Sir David Mason, and Professor Merriman of Harvard. Madame Curie received a special ovation. She was introduced as the professor of physics and director of the Curie Laboratory of the Radium Institute in the University of Paris, a woman celebrated throughout the world for her epoch-making discoveries of radium and polonium. In company with her late husband, Dr. Pierre Curie, and M. Henri Becquerel, she was awarded the Nobel Prize in 1903; and again in 1911 she received the Nobel Chemistry Prize for her work in radio-activity. In recognition of her services to science, and in appreciation of her work for humanity, the Senate sought to do itself honour by enrolling Madame Curie among its honorary Doctors of Laws. Herr Kreisler played to the students in the Bute Hall on the afternoon of the graduation. His visit was appropriate, because of the establishment this year of a chair of music in the University.

Appointments at Aberdeen and Inverness.

Dr. Harry J. Rae has been appointed medical officer of health for the city of Aberdeen in succession to Dr. J. Parlane Kinloch, now chief medical officer to the Department of Health for Scotland. Dr. Rae is a native of Aberdeen, where, after receiving his preliminary education at the grammar school, he graduated at the university in arts in 1907, and in medicine, with honours, in 1911. In 1914 he obtained the Diploma in Public Health of Aberdeen University, and became assistant school medical officer for Aberdeenshire. Thereafter he acted as assistant tuberculosis officer, and, after a period of war service, deputy county medical officer of health. He was appointed chief medical officer for Aberdeenshire in 1925, when the scheme for the co-ordination of the medical services in the county came into operation. The directors of the Northern Infirmary, Inverness, have appointed Dr. R. C. Bannerman to the newly created full-time post of pathologist and bacteriologist to the hospital. Dr. Bannerman is a graduate of Edinburgh University, having qualified in arts in 1910, and in medicine, with first-class honours, in 1914.

The Scottish Health League.

The Scottish Health League is an amalgamation of a large number of varied interests in health education. Its president is the Duchess of Atholl, and Sir Robert Philip is one of its vice-presidents; the council includes a number of medical practitioners and dental surgeons, and there is an advisory council of medical officers of health. The aim of the league is to disseminate knowledge among the people in regard to the most efficient methods for the maintenance of health and the prevention of illness. It does not seek to relieve local authorities of their responsibilities, but to establish a link between the public and the responsible officers of the authorities, so that the existing powers may be used to the utmost advantage. To attain this object branches of the league are being formed throughout Scotland. Posters, leaflets, health books, lantern slides, films, and lecture outlines are being distributed from the headquarters of the league, and lecturers on health education matters are sent out on request. An attractive periodical, *The Scottish Health Magazine*, now in its third issue, is published monthly, price 6d., at 29, Cadogan Street, Glasgow, C.2, under the editorship of Dr. M. Menzies Campbell.

Treasurership of the Edinburgh Royal Infirmary.

Mr. William Strathie Caw, who has given forty-nine years' loyal service to the Royal Infirmary of Edinburgh, is retiring from the office of treasurer and clerk at the end of the year. The managers have appointed Mr. Henry Maw as his successor. Mr. Maw, after receiving a training as an accountant, took up hospital administrative work in 1912, and acted for eight years as accountant and assistant secretary of the Bradford Royal Infirmary. Since 1920 he has been secretary of the Clayton Hospital at Wakefield, where he has acquired a high reputation as an organizer and administrator.

England and Wales.

Honours for Sir Ronald Ross.

On the evening of June 21st Sir Ronald Ross received the Manson Medal at the hands of the president of the Royal Society of Tropical Medicine and Hygiene, and the triennial Gold Medal of the West London Medico-Chirurgical Society at the hands of the president of that body. In both places the presentation was made in very felicitous terms and to the accompaniment of hearty applause from those assembled. Sir Ronald Ross, who was obviously in a very weak state of health, contented himself with a word of thanks in each instance. At the Royal Society of Tropical Medicine Dr. G. Carmichael Low recapitulated some of the important landmarks in the work of Ronald Ross. When he began work in India in 1889 Sir Ronald was attracted to the study of malaria, a disease which was not only very prevalent there, but was one of the main causes of death among the natives of the country. Returning to England on leave in 1894 he had the good fortune to meet Manson, and to listen to the latter's hypothesis that "the flagellate bodies are stages in Leveran's parasites which produce motile spores for the purpose of infecting mosquitos which happen to suck the blood of patients." Struck by this idea, and stimulated by his conversations with Manson, Sir Ronald, on his return to India in 1895, started on his world-famous researches, which were ultimately to prove the hypothesis suggested by Manson and to give the world the true history of the malarial parasite in its passage from man to man. Dr. Low went on to say that the story of the difficulties, heart-breaking disappointments, and laborious and trying work carried out in an exhausting tropical climate, crowned eventually by complete success, was to be found in Sir Ronald Ross's memoirs; and no one reading that account could fail to appreciate the grit, energy, determination, and ability of the man who carried it

out. The remarkable feature of his work was that he completely elucidated the whole cycle of the malarial parasite. This had stood to the present day almost exactly as he described it, and had not required altering in any respect. So often did it happen that a big discovery by one man was changed out of all recognition by later investigators, who took the major share of the credit. Sir Ronald Ross had had many honours for his work, but Dr. Low ventured to think that the Manson Medal would rank high among them because it associated his name with that of his old friend who had suggested the hypothesis and had helped and encouraged him in every way during his work in India. It would seem strange, therefore, and incomplete, if a Manson Medal did not include the name of Ross among its recipients, because the names of these two great men would go down to posterity together as the conquerors of malaria. At the West London Medico-Chirurgical Society, on the occasion of the Cavendish Lecture, reported at page 1164 of this issue, Dr. H. H. Sanguinetti handed to Sir Ronald Ross the Gold Medal, and in doing so said that the society honoured itself in honouring one whose work had been of such immense value to the Empire and to the world. It was due to his work that, for example, it had been possible to rid the Panama Canal zone of disease and to make safe and healthy vast rubber plantations.

Royal Society Conversazione.

At the second summer conversazione of the Royal Society, held on June 19th, the four rooms at Burlington House were, as usual, full of interesting and varied exhibits for the entertainment of Fellows and guests. The Strangeways Research Laboratory again contributed a collection of microscopic specimens illustrating recent work on embryonic development *in vitro*. The isolated femurs of six-day fowl embryos show a remarkable capacity for self-differentiation. When removed from the body and cultivated in a watch-glass containing suitable culture-medium the femurs may increase to more than three times their original length, and they also undergo what appears to be a normal anatomical and histological development, including ossification. Further, just as in normal development, the femurs cultivated *in vitro* synthesize a phosphatase, which may effect calcification by liberating inorganic phosphate from phosphoric esters. On cultivating undifferentiated three-day embryonic limb-buds in a watch-glass these have been found to differentiate to form small-celled cartilage, but not enlarged cartilage cells, osteoblasts, or bone, nor is phosphatase synthesized by these explants. This work was by Dr. H. B. Fell and Dr. R. Robison. Further work by Dr. R. G. Canti and others, under the auspices of the same laboratory, showed the effect of radium on mitosis *in vitro*. Tissue cultures were exposed for a short time to radium and subsequently incubated at 37° C. Irradiation was found first to cause a reduction in mitosis, followed by a compensatory increase, bringing the mitotic figures to a point largely in excess of the controls, and, finally, after six hours, mitosis fell to normal. The effect of temporary exposures of the cultures to low temperatures was strikingly similar to that seen with radium. Tissue cultures exposed to x rays for a short time showed a reduction in the number of cells in mitosis, and, for a longer time, a degeneration and breaking-down of individual cells. Some very interesting exhibits came from the natural history departments of the British Museum. These included fossil specimens of extinct mammals and fish, the colouring and patterning of certain woodpeckers, another exhibit illustrating the similarity of form that may occur in insects belonging to different orders, as well as in widely different sections of the same order, also a model of a remarkable abyssal cephalopod, the specimen being obtained at 750 fathoms in the Pacific, and representing the most primitive member of the octopoda, or an intermediate between that order and the decapoda (squids and cuttle-fish). Then Dr. H. Eltringham illustrated a wonderfully minute study on the scent-producing organs of insects. Scents are produced and employed by insects in courtship and in defence to an extent difficult for the ordinary person to realize. The very complicated organs found in the heads of minute caddis flies—the whole head is rather less than one-fiftieth of an inch across—were quite amazing, as seen in Dr. Eltringham's models. The Potato Virus Research Station, Cambridge, showed how it was possible to alter the character of the virus of potato mosaic by passing it through another plant host, and also by using different methods of transmission. When the virus is inoculated into tobacco with the needle an infectious disease known as "ring-spot" is produced, and progressive needle inoculation of ringspot through successive tobacco plants increases the virulence of the virus until it becomes almost lethal to the plant. When ringspot is transmitted to healthy tobacco by greenfly instead of by needle dark green mottled lines are produced, and not rings, and when either of these diseases is returned to the healthy potato an intensified and highly infectious form of the original mosaic is produced, showing that passage through the tobacco plant has induced a change in the nature of the virus. There were also shown at Burlington House many experiments in physics of great interest. Mr. J. E. Barnard illustrated his method of dark-ground illumination with ultra-violet light in the microscopy of very small bacteria, beyond the limit of optical achievement of the objectives employed. Among other exhibits was a cosmetic found in the tomb of Tut-ankh-Amen at Luxor, which had been carefully analysed, and might be supposed to have consisted, originally, of nine-tenths of neutral animal fat and one-tenth of some resin or balsam. Mr. A. A. Campbell Swinton's photographs of eminent scientific men were also of great interest. Mr. Swinton has been fortunate enough, as an amateur photographer, to have had as his sitters all the most celebrated scientific men of this country since Huxley, of whom he has a photograph, taken by the wet-plate process, dating from 1877.

Livery Dinner of the Apothecaries' Society.

At the Livery Dinner of the Society of Apothecaries of London, held at Apothecaries' Hall on June 18th, the Master, Lieut.-Colonel C. T. Samman, spoke of the movement lately entered upon by the Society. In particular, a committee had been set up to give advice in regard to light treatment, its object being to enable doctors, wherever they might be, to find some practitioner in whom they could place implicit trust when such treatment was required. Another new departure consisted in infusion of fresh blood into the Court, and he hoped that in that way the interest of the Society and the profession would be furthered. A little more than a year ago, he said, it had been discovered that the woodwork of the Society's hall had been ravaged by the death-watch beetle, and but for the skill of the surveyor, Sir William Wells, absolute disaster would have followed. The fate threatened was averted at a cost of about £20,000, and a generous response had been made to an appeal for funds which the Society had sent out to all its members. There was still, however, a large deficit, which he invited the Livery to make good. In the course of the evening Dr. R. Whiteside Statham presented Sir William Hale-White to the Master, to receive the honorary freedom of the Society. There was a close similarity, said Dr. Statham, between the presentation that was being made that evening and one which had taken place three hundred years ago; in the year 1629 Thomas Johnson, a great Royalist and an authority on the properties and actions of drugs, had been admitted to the freedom of the Society; Sir William Hale-White in his turn was the greatest living authority to-day on therapeutics. Like his prototype in the seventeenth century, he had served in His Majesty's Forces, and the Society, by admitting a man of his distinction, was honouring the profession and itself. Sir William Hale-White, in replying, said that he all the more appreciated the honour conferred on him because, under the ordinances, the number of honorary freemen was limited to ten, and frequently the full complement did not exist. Sir Ewen J. Maclean, president of the British Medical Association, and Mr. Francis Weston replied to the toast of "The Guests," which had been proposed by Sir George Buchanan, the junior warden, and the toast of "The Livery" was replied to by Sir George Makins and Dr. J. P. Gibbons.

Centenary of King's College, London.

The Duke and Duchess of York inaugurated, on June 25th, the centenary celebrations of King's College, London. The ceremonies continued during the week and included a thanksgiving service in Westminster Abbey and the dedication by the Archbishop of Canterbury of a new wing of the students' hostel in Vincent Square, Westminster. King's College was a pioneer in the provision of hostels for students, and in addition to the delightful building in Westminster, which is for men, it has a women's hostel at Bayswater, and another men's hostel at Denmark Hill. The college buildings in the Strand have some very interesting medical associations. Here Lister, it will be remembered, held a professorship, and in the neuro-pathological laboratory Sir David Ferrier carried out much of his experimental work. The University of London, to which the college is affiliated, continues to teach in King's Buildings the preliminary and intermediate medical studies, but King's College Hospital, which was formerly in close proximity, was removed many years ago to the south-eastern suburbs. Other notable names associated with the college history are, in physics, those of Clerk Maxwell and Wheatstone; in literature, Thomas Hardy and Edwin Arnold; and in theology, Wace, Gore, and F. D. Maurice. Both King's and University College, which date from the same period, suffer from the fact that they possess neither the air of antiquity, like Oxford and Cambridge, nor that of modernity, like the newer provincial universities, and for that reason, although their achievements have been very noteworthy, and they have supplied a stream of brilliant men to the industries and professions, they have not attracted endowments. King's College has been hampered by lack of room. A new building has lately been taken above the adjacent underground station of Aldwych—a much less classical environment than the wing of Somerset House, where the main building is situated—and here several of the departments are housed. These of chemistry and anatomy, however, still suffer from cramped quarters. It is hoped, in view of the interest which the centenary may be expected to arouse, that not only will it be possible to obtain the funds necessary for completing the hostel extension at Vincent Square, but also those for rebuilding one of the blocks in the Strand so as to provide an extension for the department of chemistry, and a new anatomy building above it. It is stated that the number of students at King's has doubled since the war, and that it includes at the present moment over a hundred visiting students from the Empire overseas and foreign countries.

Ireland.

The Changing Foundations of Materia Medica.

A PRESIDENTIAL address of unusual range and interest was delivered from the chair at the sixty-sixth annual British Pharmaceutical Conference which has been held in Dublin during the past week. Mr. R. R. Bennett, F.I.C., gave in outline an account of some of the more striking changes in materia medica wrought by progress in chemistry and biochemistry, in physics, in physiology, and in the science and practice of medicine. The present, said Mr. Bennett, was an age of standardized products, and isolated active principles had to a considerable extent replaced the parent drug. He mentioned morphine, cocaine, atropine, quinine, and emetine as a few of the older well-known examples of the active plant alkaloids which in large measure had replaced in medical practice the drugs wherein they occurred. More recently ergotoxine had been made from ergot on a commercial basis. Among the achievements of recent years was the replacement of the active principles of certain natural products by identical substances synthetically produced at a cost which compared favourably with that of the natural article. The price of synthetic thyroxin, Mr. Bennett said, was half that of the natural product obtained from the thyroid gland. Another case in point was the replacement of the natural ephedrine by the synthetic product, though the latter did not possess the same therapeutic activity as the natural alkaloid. Both in the animal and in the vegetable world Nature effected her syntheses within a very small range of temperature and with very mild reagents. Fusions with alkali, treatment with powerful dehydrating agents, and sealed-tube reactions under pressure were unknown to her. The syntheses of the laboratory were invariably performed in a manner which would destroy the apparatus in which nature works. Nature also possessed the secret of optical activity, and left to art the synthesizing of optically inactive forms only, but most of these optically inactive forms could now be resolved. Mr. Bennett went on to point out that in addition to the substances occurring naturally in the vegetable and animal kingdoms there were an enormous number possessing valuable medicinal properties which were obtained solely by a synthetic chemical process. From the synthesis of urea by Wöhler just a hundred years ago to the recent synthesis of thyroxin, vast numbers of organic compounds had been synthesized. Many synthetic local anaesthetics had been introduced as a result of the search for substitutes for the natural alkaloid cocaine. The toxicity of the members of this group—including ethocaine, borocaine, eucaine, and stovaine—was less than that of cocaine, but their anaesthetizing power was less also. Avertin, a tribrom-ethyl alcohol, was the latest addition to the drugs at the disposal of the anaesthetist. A great amount of work had also been done in the development of the use of synthetic dyes in therapeutics. The study of dyestuffs had been directed to the treatment of disease due to protozoal infection, and some very useful compounds had been discovered. Trypan blue had proved particularly successful in the treatment of "red water" fever in cattle. Some of the dyestuffs first studied for their trypanocidal effects had been found more useful as bactericides, as, for example, acriflavine and auramine. Mercurochrome had resulted from the search for an actively antiseptic organic mercury compound possessing the antiseptic properties of the inorganic mercury salts, and at the same time free from the disadvantages of the latter in the way of destructive action upon animal tissue. Tetraiodophenolphthalein had been successfully applied in x-ray technique for cholecystography. Again, the control and cure of protozoal diseases by means of various organic compounds of arsenic and antimony was an achievement of outstanding importance. Mr. Bennett mentioned also the work done on chemotherapy, and the need for a closer alliance of chemical, biochemical, pathological, and clinical workers in this direction. A start had been made, he said, through a permanent committee of chemists and biologists, in organizing chemo-therapeutic research, and a separate committee would organize and direct the necessary clinical trials of substances which were likely to be of importance in medicine. An experiment of great interest in this connexion was the establishment of a chemical research laboratory at Teddington, under the general scheme of work directed by the Department of Scientific and Industrial Research; here work will be done in collaboration with the Medical Research Council, with the object of obtaining experimental evidence of the relationship between chemical constitution and physiological activity.

Ballinasloe Mental Hospital.

In the course of the annual report presented by Dr. John Mills, resident medical superintendent of Ballinasloe Mental Hospital, the following outstanding facts are mentioned. Attention has frequently been drawn to the advantage to the patient of seeking treatment at the early stage of the disorder, but the inrooted prejudice against admitting that there is any insanity in the family still exercises a potent influence in deterring relatives from seeking the provided means of treatment, and this is often not used until some indefensible unsocial act is committed which brings the patient within the terms of the Dangerous Lunatics Act, under which 220 of the total number were committed. In this connexion Dr. Mills draws attention to the establishment by the governors of the Royal Edinburgh Asylum of two hospitals within their area where voluntary patients are admitted as to an ordinary hospital, and there receive the treatment most appropriate to their condition; many such patients escape

thereby what is still regarded as the stigma of certification. With the advance of knowledge of mental disorder this method of treatment is bound to secure a wider field of application than it has yet attained. In the admissions to Ballinasloe during the year under review the principal causes of insanity assigned were heredity in forty-eight cases, congenital mental defect in fifteen, puberty and adolescence in twenty-four, senility in twelve, mental stress, sudden or prolonged, in twenty-two, lesions of the brain and epilepsy in six, and disorders of gastro-intestinal system in fifteen. In thirty of the cases no principal factor could be ascertained. Dr. D. L. Kelly, inspector of mental hospitals, in the course of his report, mentioned that the general health of the patients at Ballinasloe was good; the number confined to bed was not unduly high. Seclusion was scarcely ever resorted to, but one patient had constantly to be restrained by the jacket for violence and continual resistance. He saw all the patients, paying special attention to the recent admissions; they appeared suitable cases for treatment. Some patients with whom he conversed spoke highly of their food and of their treatment generally; they appeared to be contented and comfortable. The appearance presented by the male patients was creditable to the staff. They were dressed in good materials; their clothing was sound, clean, and tidy, and their boots were polished. Indoors, the non-workers should in all cases be provided with slippers or unnailed boots. The female patients were, as usual, extremely neat and tidy. A great variety in the design of their attire was allowed, and they used their own taste in making such articles of personal dress as crochet collars, etc. This practice was to be approved of. Every endeavour was made to find employment for the patients. The men were principally engaged on farm work and at general tidying up round the institution; some worked as tailors, bakers, stokers, etc. The women were to be found at work in all divisions, sewing, knitting, rug-making, and repair and fancy work; a large number found employment in the laundry and the kitchen. The work turned out in the laundry was highly satisfactory, and the patients worked under favourable conditions.

Proposed Home for Defective Children in Belfast.

A report of a deputation from the Belfast guardians to the Ministry of Home Affairs for Northern Ireland regarding the provision of a central home for afflicted children was presented at a recent meeting of the Belfast guardians. Miss Gaffikin (the report stated), speaking for the deputation, said that their object was to impress upon the Ministry the desirability of providing one central home for defective children, whether educable or non-educable. The board of guardians would have no objection to adult mental defectives being received in the same home. Miss Gaffikin also stated that the guardians believed that the establishment of a central home was desirable on the ground of economy and of efficiency, and that it would not be in the interests of the public or of the children that the home should be carried on under the Poor Law. The home contemplated should be for the whole of Northern Ireland. The guardians expressed their willingness to co-operate in any scheme that might be put forward for running the proposed institution. Major Harris, secretary, Ministry of Home Affairs, pointed out that about 500 children had to be provided for. The deputation assured the Ministry that the guardians were prepared to share the responsibility for the cost, provided that the education authority would be responsible for educable children of school age. Major Harris later stated that the whole matter would receive careful consideration, but that it could not be promised that steps would be taken immediately.

Sunshine Home, Stillorgan.

The annual meeting of the Sunshine Home, Stillorgan, was held recently, when Sir William Wheeler presided; the Governor-General was present. The annual report stated that during the year thirty-one children were discharged cured, this number, an increase of thirteen over that of the previous year, bringing the total of cured cases to seventy-six; three were improved. The number of cases admitted during the year was forty-six, and the number undischarged on February 28th was twenty-four. There was accommodation for twenty-four children, which, however, was far from adequate, and the committee looked forward to the time when it could deal with cases of rickets as they arose. At present the most urgent cases were admitted at the first opportunity; less urgent cases had to be kept waiting owing to lack of room, with the result that the children became worse and on admission were incurable. The committee, therefore, appealed most urgently for funds to build, equip, and endow an additional ward to accommodate at least twelve children; their greatest need was more annual subscribers.

India.

Organization of Medical Research in India.

IN an article on the organization of medical research in India, published in the *British Medical Journal* of December 1st, 1928 (p. 1001), some account was given of the findings and recommendations of the committee which went out to India in the winter of 1927–28, with Sir Walter Fletcher as chairman, to study this problem. After considering the matter in all its bearings, the Fletcher Committee found at Dehra Dun an appropriate site for the Central Medical Research Institute. It is understood that a number of copies of the Fletcher Committee's Report were printed more than a year ago by order of the Government of India, but this document has not yet been issued for general circulation. The All-India Conference of Research Workers passed a resolution last winter urging the Government to publish the report forthwith, and a further indication of the growing demand for its publication is given in a printed communication lately received from the Bombay Medical Union. This consists of a long letter, dated May 16th, addressed by Dr. G. V. Deshmukh, President of the Union, to the Secretary of the Department of Education, Health, and Lands of the Government of India. The letter expresses regret "that though the Fletcher Committee signed their report in March, 1928, and that though the All-India Medical Congress held at Calcutta urged the circulation of this report last December, and that though my committee submitted a similar request last January, Government have not yet published this report and the evidence collected by the Fletcher Committee. Such an attitude on the part of the Government can only serve to increase the suspicion which the independent medical profession is driven to entertain as to the reasons why the medical advisers of Government are pressing for locating the Central Medical Research Institute at Dehra Dun and rushing this plan through."

Extension of Bombay Hospitals.

At the end of 1925 a Hospital Fund for Bombay was inaugurated under the presidency of Sir Leslie Wilson, with a view to supplementing the hospital accommodation in this city by 2,000 beds, and then to continue on the lines of King Edward's Hospital Fund for London. The annual report of this Fund for 1928 contains information about the active work that is being done in connexion with enlarging some of the existing hospitals. Thus, it is proposed to rebuild the Cowasjee Jehangir Ophthalmic Hospital, bringing its accommodation up to 100 beds. A gift from the trustees of the Sir Sassoon David Charity Trust will result in the provision of beds for Jewish patients in a special pavilion of the Jamsetji Jeejibhoy Hospital. A new hospital for children has been erected, this being the first new institution completed under the auspices of the Fund. The extension of certain other hospitals is under consideration, and the Fund is meeting half the cost of constructing a ward of 16 beds for venereal patients at the King Edward Memorial Hospital. On March 19th the Governor of Bombay laid the foundation stone of an extension to the Bai Yamunabai L. Nair Hospital, which is situated in a very thickly populated part of Bombay. The Governor in his speech, commented on the growth of this hospital and of the medical college attached to it, and expressed regret that it had been found impossible for

the Government to co-operate financially, owing to the heavy pressure of other commitments. This hospital was opened in May, 1925, and has about seventy beds. The numbers of both out-patients and in-patients are increasing rapidly, and the institution has recently been approved by the Bombay Presidency Nursing Association for the training of probationer nurses.

Progress of Medical Treatment in Nepal.

A short but interesting account of the history of scientific medicine in the secluded kingdom of Nepal is contributed by Dr. Indra Man, assistant surgeon to the Bir Hospital, Katmandu, Nepal, to the April issue of the *Indian Medical Record*; he traces its beginning to the period of the Indian Mutiny, when the Maharaja Jung Bahadur appointed a Dr. Khetra Mohan Mukherji as his palace physician. From the biography of this officer it appears that in those days the Maharaja made use also of the services of the English surgeon attached to the British Residency, but no public medical institution existed for the indigent and needy. The Maharaja's nephew, Bir Shum Sher, similarly employed the services of a family physician, and was the first to establish a hospital in Nepal—namely, the Bir Hospital at the capital, Katmandu, which comprised two separate buildings for the two sexes. Later another public hospital was opened at Birganj, a frontier town. More rapid progress followed in the provision of scientific medical assistance with the coming into power of the present prime minister, the Maharaja Chandra Shum Sher, who established the Sri B. Chandra Loke Hospital at Bhadgaon, a large town six miles from the capital. He next provided a hospital at Bhimphedi, and later decreed that there should be one hospital in each district, so that there are now more than two dozen hospitals in operation in the kingdom. The prime minister has recently caused a military hospital to be constructed; in the current year he is arranging for the establishment of a dispensary at Patan, and a leper asylum at Firping, under a Bengali medical practitioner trained at the State expense in the Calcutta School of Tropical Medicine. The prime minister has also arranged for several Nepalese youths to receive a full course of medical education in British India, so that the staffing of these institutions may be secured. The Bir Hospital under his regime has been enlarged and its trained staff has been increased. Dr. Indra Man comments on the very considerable change with regard to scientific medical treatment which has occurred among the very conservative Nepalese in the course of the last fifty years. They were at first highly suspicious, and avoided the hospitals, but they are now responding to the commendable encouragement given by the Government and are coming freely for treatment. Education is being improved and knowledge about public health is spreading; one of the latest steps to be taken is the allocation of a sum of money for the construction of a sanatorium for tuberculosis.

Medical Journalism in South India.

As previously mentioned in these columns, the monthly medical journal known as *The Antiseptic* recently completed twenty-five years of existence, having been founded by Dr. U. Rama Rau, with the late Dr. T. M. Nair as its first editor. Dr. Nair continued as editor until his death in 1919. The April issue of this periodical takes the form of a silver jubilee number, and Dr. U. Rama Rau, the present editor, contributes an account of its history, with especial reference to the interest that has been taken in the welfare of assistant medical officers. At its inception there was no considerable scientific medical journal in South India, and, consequently, it carried a heavy load of responsibility as regards the publication of medical research and the championing of various causes; one of the first of these was a defence of vaccination against an attack based on a case of death due to the subsequent infection by tetanus of a vaccination wound. Other matters of public interest with which *The Antiseptic* has concerned itself are: medical education in India and the establishment of a register; sanitary conditions in large towns; hospital abuse; and various medical problems in the Madras Presidency. The silver jubilee issue contains messages of congratulation from prominent medical practitioners in Great Britain as well as in India.

Correspondence.

X-RAY TREATMENT OF EXOPHTHALMIC GOITRE.

SIR,—To those who lightly skim through the *Journal* the argument of Dr. Charles S. D. Don (June 22nd, p. 1103) in his attempt to evaluate statistically x-ray treatment and operation in exophthalmic goitre may appear convincing. To those, however, who read between the lines I am afraid that some of the abuses as well as the uses of statistics are illustrated: for his material is limited to twenty-five cases of each series, all the factors are not given or analysed, and his results are not compared critically with those of others in the same field.

Thus the patients for whom operation was considered were put to bed, and iodine was administered till the basal metabolic rate had come down to about +30 per cent. If after three weeks the rate remained above 30 per cent. the case was regarded as inoperable. Are we to infer that x-ray treatment was tried in these rejected cases?

If the x-ray series of cases (whether their severity was equivalent to that of the operable or not) were treated as *out*-patients, and without the advantage of iodine administration (no data are given on these points), these factors alone would render them not truly comparable with the operated on series; but in addition, compared with the doses advocated by most radiologists, too small x-ray doses appear to have been given. "A quarter of an erythema dose" is considered by some to be a "stimulation" dose: in any case, however useful such a dose may prove at the beginning of treatment where often-repeated doses may be given, it seems an inadequate dose for the later widely spaced treatments. Further, in Dr. Don's data we are not told if the x rays were applied only from the front in one area, or if from each side; nor are we told if the thymus was irradiated as well as the thyroid, though this is of considerable importance.

Dr. Don says that "little has been published in this country on x-ray therapy," but A. E. Barclay[1] has shown in 300 private cases lately about 90 per cent. success, and I[2] have shown out of 107 cases an 82 per cent. success with x-ray treatment. Barclay's dose was a third of an erythema dose from each side of the neck, including the thymus area, given twice a week at first, later weekly, and at longer intervals. (Filter 2 mm. Al.) The dosage I had used was "one-half to two-thirds of the dose which will produce an erythema on the sensitive skin of the exophthalmic patient." If the Sabouraud pastille be used this is one-half to two-thirds of a pastille with 1 mm. Al filter, 120 or more kv.; or with 3 mm. Al one to one and one-third of a pastille. With the Holzknecht scale (as given by Lenk) this is from 2½ to 5 H.

It is convenient to group patients into several grades as regards chronicity, mildness, size and hardness of the thyroid, and whether other conditions are satisfactory, and to treat accordingly. Patients here, more than with many other disabilities, need to be individualized; and routine treatments will meet with only a small measure of success. If adequate x-ray dosage be given, x-ray treatment gives results second to none.—I am, etc.,

London, W.1, June 22nd. J. H. DOUGLAS WEBSTER.

TUBERCULOUS ADENITIS.

SIR,—I was much interested in Mr. Gordon Bruce's article on enlarged cervical glands in the *Journal* of June 8th (p. 1030), as during my service as civil surgeon in the Punjab I had a great deal of clinical experience in this subject. I can now only state from memory, but during the last four years I was in Amritsar I performed at least 400 operations for this condition.

This disease is very common in the Punjab; not only does one get cervical adenitis, generally of both sides, but also tuberculous axillary and inguinal glands. Tuberculosis of all kinds is very prevalent in the Punjab, but whereas surgical tuberculosis is found both in villagers and town-dwellers, tuberculosis of the lungs is confined entirely to

[1] A. E. Barclay and F. M. Fellows: *Lancet*, March 30th, 1929, p. 633.
[2] J. H. Douglas Webster: *British Medical Journal*, June 15th, 1929, p. 965.

the dwellers of the crowded and insanitary towns, and in my experience is invariably fatal. Surgical tuberculosis, however, especially among the villagers, is quite amenable to active treatment, and of these conditions the treatment of tuberculous adenitis by excision is eminently satisfactory—in fact, it is the only treatment worth considering. The results, even in very extensive disease—and the cases one gets are often far advanced—are excellent. Of course, one cannot follow them up in India as Mr. Bruce can in this country, but the immediate results are good. I certainly think that patients would not come to one for treatment if the permanent results were not also good; for the Punjabi peasant is no fool, and although he has not much faith in European medicine he appreciates to the full the benefits of surgery.

I can only remember two fatal results during my service. One was from delayed chloroform poisoning in a girl of 6, who had both sides of the neck extensively involved. I was tempted to do both sides at one sitting, and she died of delayed chloroform poisoning two days later. The other case—one of my earlier ones, which was due perhaps to inexperience—happened in 1908. This patient was a fine young Punjabi Mohammedan, the son of a leading man in the district, who had enormous masses of glands on both sides of the neck. I excised those on the right side successfully, and he returned in good health two months afterwards to have the other side operated on. I had nearly finished when I discovered a few glands left deep down in the subclavicular triangle. I was pulling on what I thought was an adhesion when there was a gush of venous blood, and I found that I had torn one of the communicating veins from the internal jugular. Eventually I had to tie the jugular in two places. The wound healed satisfactorily, but the patient returned two months later with advanced tuberculosis of the lungs, from which he died. I have no doubt that owing to this unfortunate accident a systemic infection took place. After this I never cut through any adhesion without first clamping it.

I have never done any injury to the nerves, and can confirm Mr. Bruce's opinion that the mass of glands around the spinal accessory should be split up. Also in all extensive cases the borders of the sterno-mastoid should be carefully defined before the deep dissection is proceeded with; this muscle forms a valuable landmark, and should never be injured. The most useful instrument for dissecting out the glands is a pair of blunt-pointed scissors curved on the flat; I never used the knife for this purpose, but removed the glands by a combination of leverage and snipping with the scissors. I learnt this originally from that great surgeon the late Mr. Jacobson, who taught me how to do the operation. His well-known dictum was to treat all tuberculous disease as malignant, and to remove it whenever possible.

A drainage tube should always be inserted for the first two days, as there is generally considerable oozing, specially when the adhesions are extensive. If this is not done healing will be delayed and suppuration may take place. It is unwise to use any of the various forms of gland forceps: they very rarely hold properly, and in most cases lead to rupture of a caseating gland and infection of the wound.—I am, etc.,

Streatham Park, S.W., June 17th. H. C. KEATES, M.D., B.S.Lond., Lieut.-Colonel I.M.S.(ret.).

CLASSIFICATION OF RHEUMATIC DISEASES.

SIR,—The letter by Dr. M. B. Ray, criticizing Dr. A. H. Douthwaite's nomenclature of these conditions, is really rather amusing, and shows the utter fog there is on the subject, for if Dr. Ray cannot follow Dr. Douthwaite I am sure Dr. Douthwaite cannot follow Dr. Ray.

At the discussion on chronic arthritis at the Royal Society of Medicine in November, 1923, and on other occasions, I have urged that the term "rheumatoid arthritis" be scrapped, for the following reasons:

1. It is used by some clinicians to include all forms of chronic arthritis, and not only arthritis, but fibrositis and such conditions as hallux rigidus and bunion.
2. It is used by others to signify all forms of infective periarthritis.
3. The general public have got hold of the term, which they associate with an incurable disease. How frequently one is asked in one's consulting room, "Have I got rheumatoid arthritis?" and patients are very much depressed if they are told they are suffering from rheumatoid disease when they are suffering from fibrositis or chronic villous arthritis—that is, climacteric arthritis.

The term "rheumatoid" must go. Let us carry on with the nomenclature of the Ministry of Pensions. Group C, Chronic Joint Changes, consists of four subgroups: No. 6, rheumatoid arthritis (infective periarthritis); No. 7, osteo-arthritis; No. 8, gout; No. 9, chronic joint changes unclassified. With these four subgroups one may have as many subdivisions as one likes—for instance, under No. 6, a subdivision for spondylosis rhizomelique, another for Still's disease, and yet a third for atrophic arthritis. Under No. 7, osteo-arthritis, one may have a subdivision for spondylitis deformans, and another for malum coxae senilis, and so on.

I have referred to atrophic arthritis. I believe that there is a special entity confined, as Strangeways also pointed out, to the female sex. It attacks young women at the commencement of the reproductive period. This is the type of case referred to by Dr. J. A. Glover and quoted by Dr. Ray, and I am glad to see that Dr. Douthwaite recognizes this variety also as distinct from infective arthritis, which is so commonly called rheumatoid. These cases are limited in number, and only represent about 9.6 per cent. of what is commonly called the rheumatoid group (infective arthritis and chronic villous arthritis). Chronic villous arthritis (or climacteric arthritis) I recognize as still another variety, which if not treated may tend to become osteo-arthritis, but never what is commonly called "rheumatoid." I am convinced that confusion in the nomenclature will continue until we get rid of the term "rheumatoid."—I am, etc.,

Harrogate, June 18th. G. L. KERR PRINGLE.

IMMUNIZATION BY TUBERCULIN.

SIR,—The great interest of the medical profession in tuberculin immunization is shown by the large number of letters I receive on the subject.

A full description of my method was published in the *British Medical Journal* of April 23rd, 1921, and I have nothing new to add to it. Metchnikoff wrote, in 1903: "In all the bacteriological institutes and laboratories search is being made for some vaccine or serum which will arrest a disease that in many cases Nature herself cures. But the results amount practically to nothing." We have reluctantly to admit that we are in much the same position to-day. In my judgement we should concentrate our activities more on the prevention of tuberculosis, and this can be accomplished by producing some active immunity in children who are associated with cases of open tuberculosis.

The method adopted by Calmette is scientifically sound, but it is open to objection on account of the possibility of reactivation of the living attenuated bovine bacilli in the body of a young child. Moreover, it is proved that immunity can be produced by dead bacilli, as is shown by the work of Petroff and others in the *Journal of Immunology* for March, 1929. The brilliant work of Sir Almroth Wright has given to the world an antityphoid vaccine which is prepared from dead bacilli of low virulence.

I would like to suggest to all tuberculosis officers and others engaged in this work the advisability of immunizing all children who are in association with cases of pulmonary tuberculosis. Two injections only are necessary, the proceeding is perfectly safe, and I have never observed any untoward symptoms. After a long experience, I am convinced that this is our best method of protecting the future generations of children against this deadly disease.—I am, etc.,

London, June 22nd. NATHAN RAW.

GAS-OXYGEN ANAESTHESIA.

SIR,—In your issue of June 15th (p. 1099) appears a letter from Mr. E. J. Chambers of Doncaster. It would be of interest to know the form of gas-oxygen apparatus he uses. It would seem strange, if the apparatus devised by Mr. Boyle had done so much harm, that it should still be used and taught in the leading teaching hospitals in

London. Further, Mr. Chambers states that to call it a gas-oxygen apparatus is a misnomer, as it is really an ether apparatus for use in conjunction with gas.

I have always understood that the very foundation principles of the apparatus were that it should be used for gas and oxygen, and the ether employed merely as an occasional accessory anaesthetic when, and if, necessary. I submit that when patients have had gas-oxygen anaesthesia administered by means of Boyle's apparatus, combined with so little accessory ether as to be conscious when leaving the theatre, those patients can be described for all practical purposes to have had a gas-oxygen anaesthetic.

I entirely agree with Mr. Chambers in his plea for the more generalized use of gas-oxygen anaesthesia, not only for the comfort of the patient in obviating post-anaesthetic vomiting, but also in those cases where the inhibition of other anaesthetics would probably tend to retard recovery. It is hard to agree, however, with his suggestion that gas and oxygen should be used for all cases of surgical work, and for all types of patient. Surely the old maxim, "Routine anaesthesia is bad anaesthesia," is as true now as ever.

In conclusion, I venture to suggest that the best results from the use of Boyle's apparatus can only be attained by the following: (1) careful selection of cases; (2) the greatest care in maintaining the perfect working order of apparatus; (3) meticulous attention to detail in administration.—I am, etc.,

London, W.1, June 13th. T. DE LACY WALKER.

MEDICAL ATTENDANCE ON PATIENTS IN PRIVATE WARDS.

SIR,—Will you kindly afford me space in which to describe what my Division considers to be a retrograde step in the Hospital Policy of the British Medical Association, on the treatment of private patients in private wards of hospitals. It should be remembered that these patients will be required to pay the full cost of maintenance, with medical, surgical, and specialist fees in addition. Hitherto the policy of the Association has granted to these people complete freedom of choice of medical attendant. The new policy deprives them of this right, and compels them to be under the care of the visiting staff of the hospital. In other words, the patient pays the piper and the hospital calls the tune.

The old procedure preserved the ordinary relationship of family practitioner to consultant, a relationship which is the result of long experience, and is in the best interests of the patient and the profession. The practitioner attended his own patient and was able to suggest the consultant best suited to the condition. The prestige of the practitioner was maintained and the confidence of his patient preserved. This is the present policy of the Association, and the proposed change involves the complete inversion of this relationship.

It is now suggested that the patient shall be under the "responsible care" of a member of the visiting staff. The private doctor of the patient is relegated to a very inferior position where he "should have such share of responsibility and treatment of the patient as may be agreed upon." A very slight acquaintance with the psychology of the honorary, resident, and nursing staffs of hospitals will enable one to appreciate that such a condition of things is impossible. In actual practice the family practitioner will be "frozen out," and his position and prestige in the eyes of his patient will be seriously damaged. We cannot imagine that any self-respecting family practitioner would tolerate being placed in such an invidious position.

We are faced with the two conflicting interests: the interest of the family practitioner in his patient, and the interest of the consultant in the work of the hospital. The present policy preserves that of the family doctor primarily, while the proposed new policy preserves that of the hospital consultant primarily. In Sunderland we have settled this problem by a compromise on lines which will preserve the interests of both. We have opened private wards in which patients are allowed to be under the responsible care of their own family doctor. If, however, any consultant is required, or any special work is to be done, the family doctor must call in a member of the visiting staff. This preserves the old relation of family doctor and consultant, maintains the prestige of the doctor in the eyes of his patient, and secures for the visiting staff their interest in the work of the hospital. We maintain that it is only along the lines of preserving the normal relationship of family practitioner to consultant that any co-operation is possible.

In order that the profession may have an opportunity for expressing its opinion on this question, this Division has put the following amendment on the agenda for the Annual Representative Meeting.

> "That the suggested new para. 29 (*a*) be deleted and the following paragraph be inserted:
>
> "(*a*) if the hospital has a resident medical officer or officers, and also a visiting staff which is ordinarily responsible for the care of all the patients in the public wards, the patient should be allowed to select any available registered medical practitioner as his attendant, but, if the treatment of the patient at any time involves the application of special skill or experience, then the practitioner undertaking the treatment should be a member of the visiting staff of the hospital."

The object of this letter is to stimulate a little interest in the subject, and to give representatives time to think the matter over before the meeting.—I am, etc.,

Sunderland, June 17th. R. H. DIX, Honorary Secretary, Sunderland Division.

A COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

SIR,—A great deal has been heard lately on the subject of a College of Obstetricians and Gynaecologists. The main argument advanced for this innovation is that the present standard of teaching and practice in obstetrics and gynaecology requires raising.

Surely this can equally well be achieved by (1) the granting of a diploma for obstetrics, (2) having a special examination for a fellowship in gynaecology, and (3) having a permanent representative of obstetrics and gynaecology on the committee of management of the Conjoint Board.

Although specialization is a necessity in the various branches of surgery, it is difficult to see why it should be necessary to have separate colleges. If we have a college for gynaecology, why not one for proctology, urology, etc.? Personally, I am quite content to be a surgeon.—I am, etc.,

London, W.1, June 18th. MALCOLM DONALDSON.

SPA TREATMENT.

SIR,—In to-day's issue of the *Journal* Dr. Geoffrey Holmes reverts to the question of a definition of spa treatment.

The definition which was proposed at the Annual Representative Meeting at Cardiff was not accepted. It certainly only approximates, as Dr. Geoffrey Holmes states, to the definition which he quotes, as it contains the following important addendum, which was not in the definition proposed by Dr. Dain. "However great the importance of auxiliary treatments may be, drinking and bathing in fresh natural mineral waters form the basis of all genuine spa treatment." Considerable alterations have now been made in the draft, but the definition which is put forward for consideration appears to be cumbersome and unlikely to meet with general approval.

What is the necessity at the present time for a definition of forms of treatment which are difficult to define when the word "spa" is attached to them? The only reason mentioned in the letter of Dr. Geoffrey Holmes appears to be in connexion with the proposed spa treatment for insured persons. If this is the reason, it is pertinent to inquire, if definite arrangements are made for spa treatment for insured persons, whether such treatments will only be recognized at places agreed upon by the Spa Practitioners Group of the British Medical Association and the insurance societies. If so, I consider that in the present state of our knowledge of "natural waters of

distinctive therapeutic value" the decision would be unfortunate. It is admitted that "all water properly applied has therapeutic value"; but how, in a definition such as is now proposed, can a final distinction be made between waters which have "a therapeutic value" and those having "distinctive therapeutic value"?

Does the statement "drinking and bathing in such fresh natural waters form the basis of all genuine spa treatment" mean that it is necessary both to drink natural water and to bathe in the natural water in order to have spa treatment; if so, what is the position of a recognized spa which does not possess a natural mineral drinking water? Further, has the time come for the insertion of the word "genuine" into a medical definition?

The various schemes which have been under consideration for spa treatment for insured persons deal mainly with rheumatic conditions. Evidence in reference thereto was given before the Royal Commission of National Health Insurance in 1925, and in a "Note on the treatment of chronic rheumatism in insured persons" attached to the evidence given on July 14th, 1925, it is concluded that three-tenths of sufferers from chronic rheumatism would be benefited by medicinal waters in a spa hospital, whereas the other seven-tenths would not require medicinal waters, but could best be treated by external methods in clinics. Even if this is in the main accurate, and I think it is, these external methods consist of baths, douches, packs, electricity, light, heat, massage, and exercises, which comprise a large percentage of all spa treatments, and are available at many places, other than a recognized spa.

Spa treatments comprise the drinking of water and its use for baths and douches, along with physical treatments, diet, and environment, which includes climate, air, amusement, and social amenities. It is only the use of its natural water for drinking, baths, and douches, and its climate, that are peculiar to a spa; but excluding the use of its natural water for drinking, there is no definite evidence to prove that the external use of its natural water for baths and douches is in any way specific for the treatment of chronic rheumatism, and it has been pointed out that the claims made by all British spas are extremely alike, similar conditions being treated with very dissimilar waters with apparently equal benefit. No one with experience of spa treatments will cavil at the statement that they are probably the most beneficial methods of treatment in chronic rheumatic diseases. As all these spa treatments, except the natural mineral water, which is only apparently required in three-tenths of the cases, are available at many places, it is, I consider, detrimental to progress to circumscribe the term "spa treatment" with a contentious definition.—I am, etc.,

Torquay, June 22nd. K. R. COLLIS HALLOWES.

DR. C. POWELL WHITE: AN APPEAL.

SIR,—We are writing to appeal for funds on behalf of Dr. Charles Powell White, who, as the result of a severe cerebral haemorrhage, is unable to maintain himself, his wife, and family. This position is largely due to the fact that he has devoted his life to cancer research for the benefit of the general public and the world at large. By his writings and works he has obtained an international reputation as an authority on cancer problems.

For many years he has given all his time to cancer research in Manchester for the Christie Hospital for Cancer, the Pilkington Cancer Research Fund, the University of Manchester, and the Manchester Committee on Cancer. In each of these appointments he has received only a nominal salary for a man of his eminence, and not being on the teaching staff of a university he is not eligible for any pension. Possessing the highest medical and surgical qualifications, he could have commanded a much more lucrative position in the active practice of his profession, but he preferred to use his wide knowledge of mathematics, chemistry, physics, and general natural sciences for the study of cancer, its treatment and prevention.

Dr. Powell White's work has a soundness of character and a breadth of application still only incompletely recognized. Thus it is to him that we owe the present classification of tumours—a classification which has been very widely adopted by pathologists. His other work is less generally known, since it is more mathematical and abstruse, but from it emerges the fact that certain analyses suggest that in persons suffering from malignant disease changes occur which show that some fundamental metabolic disturbance is present in this condition, and that these changes are greater than can be accounted for by the growth itself. He possesses a grip of the problem of malignant disease shared by few.

Dr. White has conducted long and tedious analyses on cancer problems which would have daunted many by their extent and difficulty, and it was in his laboratory that he was taken ill. He has a world-wide reputation as an authority on cancer, and has communicated articles on the subject to your columns. We hope that many of your readers to whom we cannot send the special letter of appeal will be able to contribute towards the fund. Subscriptions should be sent to Mr. Wilson Hey, 16, St. John Street, Manchester.—We are, etc.,

WALTER H. MOBERLY,
Vice-Chancellor, University of Manchester.
FREDERICK P. NATHAN,
Chairman, Christie Pavilion and Home.
R. VEITCH CLARK,
Chairman, Manchester Committee on Cancer.

Manchester, June 19th.

MENTAL HYGIENE.

SIR,—I was glad to see in this week's *Journal* (p. 1140) the earnest appeal by Sir Maurice Craig to the public health authorities to provide facilities for psychological treatment for the poorer classes. His letter receives additional emphasis from the striking report of the success of the Cassel Hospital, Swaylands, which is epitomized in the same issue (p. 1133). Also, on page 1131 there is a review of Dr. Newsholme's iconoclastic book on health, disease, and integration. The coincidence of these three items encourages me in the hope that we are at last on the eve of doing something to stop up this leak, which is draining the vital forces of the community.—I am, etc.,

Birmingham, June 23rd. R. MACDONALD LADELL.

PUERPERAL SEPSIS.

SIR,—Dr. Colin Craig's letter on puerperal sepsis (June 8th, p. 1057) should be of considerable service. That puerperal sepsis is produced *from* within I am fully convinced, as this offers the only explanation for a large number of cases that are seen in general practice. Although I have given up midwifery practice for a number of years, I was struck, as Dr. Craig has been, by the number of cases of puerperal sepsis I met with for which I could not find a satisfactory explanation.

In this connexion I undertook the task of examining over 300 urines of females—chemically, microscopically, and bacteriologically. I submitted the result to a meeting of the Edinburgh Obstetrical Society, and it was published in the society's *Transactions* in 1906. As it substantiates Dr. Craig's contention, it might be of interest if I briefly summarize my findings.

1. Out of every four urines examined, one contained pus and bacteria.

2. The bacteria *found were Bacillus coli*, staphylococci, streptococci, gonococci, pseudo-diphtheritic bacilli, and other rod-shaped bacilli which, at the time, I could not place.

3. Pyuria in its mildest form should be regarded as a septic condition.

4. Leucorrhoea existing with a pyuria should be regarded as a septic condition.

5. The urine of all pregnant women should be as carefully examined for pus as for albumin, as a puerperal fever may be caused by infection from the urethra.

6. The presence of the colon bacillus in so many urines and in vaginal discharges makes the probability almost a certainty that infection was from the anus.

There are other cases, however, to which I referred, that might be infected directly through the blood stream, as Dr.

Craig suggests. Dr. John Campbell of Belfast had a most interesting article in the *British Medical Journal* of September 23rd, 1905, entitled "The influence of the presence of pus in the female urethra on the progress of gynaecological and obstetrical cases," and this has a direct bearing on Dr. Craig's observations.

The articles I have mentioned appear as ancient history, but it is surprising that puerperal sepsis, as Dr. Craig points out, is still regarded as due to the sins of the general practitioner. What apparently is required is a bureau for assorting and assessing the numerous investigations that have been carried out, at considerable labour, for the furtherance of knowledge, and which are allowed to sink into oblivion.—I am, etc.,

Edinburgh, June 12th. FREDERICK PORTER.

PRURITUS ANI.

SIR,—The frequency of pruritus ani and the ease with which it is benefited by appropriate treatment makes me doubt if the causation is so obscure, or the treatment necessarily so drastic, as that suggested in Mr. Gabriel's valuable paper (June 15th, p. 1070). The doubt already assailed me twenty to twenty-five years ago, when, as a frequent visitor to St. Mark's Hospital, I heard these theories and noted the effects of treatment there. The common feature in all cases is a perianal dermatitis, and the cause, I believe, a soiling of the perianal skin after defaecation by imperfect toilet methods. Detailed attention to this factor will nearly always give relief, and at the request of medical sufferers, who had been so relieved, I published a note thereon in the *Journal* a few years ago. The anal fissure also usually yields readily to simple treatment, but confessedly I have not a wide experience of chronic cases.—I am, etc.,

Paignton, June 15th. ERNEST WARD.

Obituary.

DR. ERNEST MORTON WYCHE died on June 13th at his residence in Nottingham in his sixtieth year, after a very brief illness. He was educated at Oundle School and the London Hospital, and obtained the M.R.C.S. and L.R.C.P. diplomas in 1893. After holding various appointments, he took the D.P.H.Lond. in 1898. For eighteen months he served as surgeon on a cable-laying ship, and then went into general practice in Cambridgeshire. On the inception of the school medical service in 1908 he was appointed to South Essex, where he had to do pioneer work in a large rural area. In August, 1914, he was appointed senior school medical officer to the city of Nottingham. The service was still in its infancy, and Dr. Wyche devoted himself to extension of the work as rapidly as the difficulties of the war allowed. Careful not to encroach on the work of the general practitioner and the hospitals, he attempted to supply those forms of treatment which were otherwise difficult to secure. The expansion of the service after the war soon brought about the necessity for a bigger central clinic, and he was instructed to work with the city architect in adapting a large building to his needs. The new clinic was opened in November, 1926, and is a lasting testimony to his foresight and ingenuity. He was justly proud of the tonsil and adenoid theatre and wards, and of the dental department. He followed closely scientific research on the health of young people, and he was always to the forefront in securing for the children of Nottingham the benefits of new advances. A keen enthusiast on the importance of fresh air, he was instrumental in establishing one of the finest open-air schools in the country. He was quick to realize the value of ultra-violet therapy for the ailing child, and his committee was one of the first to install this treatment. His detailed organizing ability applied to every aspect of school medical work was especially shown in his scheme for the ascertainment of mentally defective and dull and backward children. A man who avoided personal publicity, he was loved by all who came in contact with him, from the youngest of his patients to the highest officials in the town. The members of his staff feel his death most keenly. They have lost not only a respected chief, but also a sympathetic friend. He leaves a widow, a son, and a daughter.

DR. THOMAS SIMMONS MORLEY died at Mill Hill on June 20th, at the age of 76. He was just beginning to get about after a long illness involving a series of operations, when infection suddenly lighted up in the kidneys, and he rapidly succumbed. He received his medical education at Guy's Hospital, taking the M.B. degree of London University and the M.R.C.S.Eng. diploma in 1874, and proceeding M.D. in 1878. After holding the appointments of obstetric resident at Guy's, and clinical assistant at Great Ormond Street, he joined his father in a practice at Barton-on-Humber, which the latter had established in 1837. In 1886, when his father died, Dr. Thomas Morley was left in sole charge of this extensive town and country practice. He was Poor Law medical officer, public vaccinator, and surgeon to the Admiralty, but he relinquished the former duties many years ago owing to the pressure of work. The difficulties and trials of a country practice, particularly in the days before the advent of the motor car, are only known to those who have experienced them, and he had little leisure. Nevertheless he kept wonderfully up to date, and his spare time was given to medical and general reading. He was a member of the Barton Urban District Council for some years, and had held office as president of the East Yorks and North Lines Branch of the British Medical Association, of which he was always an active member. By early training and lifelong conviction he was an ardent lover of civil and religious liberty, and served with great diligence the Church, with which he had been united in early life. He was an enthusiastic Liberal of the Gladstonian school, and was a well-known figure on the political platforms of that period. In the latter years of his work Dr. Thomas Morley was assisted by his sons, but owing to the war he was again single-handed, and when the influenza epidemic of 1918 broke out he worked day and night without falling a victim to this disease, which had nearly killed him in 1890. He retired at the end of 1921, and went to live at Bournemouth, but continued to take a great interest in the activities of the Association and in modern advances in the science to which his life had been devoted. He is survived by a widow, and three sons who are all engaged in the practice of medicine.

DR. BEPIN BEHARI GHOSH, who died on May 23rd, after a short illness, at the age of 72, was one of the oldest members of the British Medical Association in Calcutta. After a brilliant career at the Calcutta Medical College, he entered the service of the Government of India as an assistant surgeon, but after a little while relinquished his post to establish himself in private practice. During the latter years of his life he occupied a prominent position in Calcutta as consulting physician, and was vice-president of the Calcutta Medical Club. A conscientious public servant, he founded an English school in Antpur, his native village, was a trustee of the Shambazar A.V. School, and a member of the executive committee of the Calcutta Orphanage and of the district charitable society.

The death occurred on June 12th, at New Galloway, after a long illness, of JOHN COWAN, M.B. (Edin.), a well-known figure in the public life of the Stewartry of Kirkcudbright. Dr. Cowan had been provost of the royal burgh of New Galloway for nearly thirty years, and had figured prominently in county administration for nearly forty years, being a member of the county committee of the licensing court, and a justice of the peace for the county. As medical practitioner for the Glenkens he was widely known and highly esteemed. He was also prominently identified with Masonic activities, and was for many years worshipful master of the local lodge for many years. He was in his sixty-fourth year, and is survived by Mrs. Cowan and one son, Dr. J. G. Cowan, who was associated with his father in the practice.

We much regret to record the tragic death of Miss Barbara Edith May Morris, as the result of a shooting accident, at the early age of 33 years. She was the daughter of Mr. E. W. Morris, C.B.E., house governor of the London Hospital, and received her medical education at St. Mary's Hospital Medical School. She took the diplomas of the English Conjoint Board in 1927, but a breakdown in health prevented her from starting in practice, and she was convalescing at Bingham Park after a serious operation when the fatal accident occurred on June 17th.

The death occurred, on June 20th, of Dr. ARCHIBALD MACMILLAN, at his residence, Croft Park, Blantyre, Lanarkshire. Dr. Macmillan took the qualifications of L.R.C.P., L.R.C.S.Ed., L.R.F.P.S.Glas., with honours, in 1901, and the D.P.H.Camb. in 1913. He saw considerable war service, and had the distinction of O.B.E. conferred on him. At the conclusion of the war he took over the extensive practice in Blantyre formerly held by the late Dr. William Grant. Dr. Macmillan leaves a widow, one son, and two daughters.

The following well-known foreign medical practitioners have recently died: Professor HIROTA, the first occupant of the chair of paediatrics at the Imperial University of Tokyo, founder of the Japanese Paediatric Society, of which he was president for thirty-three years, and organizer of many maternal and child welfare foundations, aged 70; Professor FRANK KEIBEL, director of the Sicard Anatomical Institute, and professor of histology in Berlin University, aged 68; and Dr. SAMUEL S. ADAMS, an eminent paediatrist of Washington, aged 75.

The Services.

INDIAN MEDICAL SERVICE.

ANNUAL DINNER.

THE annual London dinner of the Indian Medical Service was held at the Trocadero Restaurant on June 19th, with Lieut.-Colonel D. G. Crawford in the chair. The guests were Dr. N. G. Horner, Editor of the *British Medical Journal*, and Dr. E. C. Morland of the *Lancet*.

THE CHAIRMAN, in proposing the toast of "The Indian Medical Service," welcomed several of the latest recruits to the service who had just finished their probationary course, and who would soon take up their duties in India. While few could hope to reach the success attained by such men as Sir John McNeill and Sir Joseph Fayrer in political and administrative work, or to write their names high on the scroll of fame, as great scientific discoverers, as two of his own contemporaries had done, he thought that the Indian Medical Service still offered a good career, with interesting work, fair pay, and a fair pension at the end. Most of those who, like himself, had passed the allotted span of man's life, would be glad to begin their careers over again. "If I had to live life over, I would live that life again." He also wished to welcome among them the representatives of the *British Medical Journal* and the *Lancet*. All the seniors, at least, in the service must know what the British Medical Association and the two great medical journals had done for the public medical services, not only for the I.M.S., but also for the R.A.M.C. and the medical department of the Navy. Whenever the medical services had been suffering from reasonable grievances, or had been in a tight place and had asked for help and support from the civil profession, the help and support required had been given fully, freely, and ungrudgingly by the Association, and by the two great medical journals.

It was now a little over three hundred years since the East India Company opened their first settlement in India, at Surat in 1609. Their factory had as staff a few senior officers, called merchants; a few juniors, starting as clerks, or, as they were then called, writers; also a chaplain and a chirurgeon. And the Indian Medical Service started, one strong! For defence they had a handful of Goanese peons. That small body of merchants and writers had grown into the great Civil Service of India, that half company of Goanese peons had expanded into the Indian army, the finest army in the world. And that Civil Service and that army, with the I.M.S. sharing in their work as a branch of the army, had built up the Indian Empire, and had given to India peace and prosperity in the place of anarchy and misery.

In 1763, just about halfway between the first beginning and the present time, the Indian Government organized their scattered medical officers, who by this time amounted to well over a hundred in number, into a graded service, with regular fixed ranks and pay: the Indian Medical Service, with its three establishments—Bengal, Madras, and Bombay. These medical officers were not commissioned officers; only the surgeon-general held a commission—the rest were warrant officers. Lord Cornwallis gave commissions to all medical officers, from the date of their appointment, in 1788. Eight years later, in 1796, furlough and pension were granted. Up to that year an officer who wished to go home had to resign the service, being allowed, as a rule, to resign, "with permission to return." The rates of furlough pay and pension granted in 1796 seemed nowadays absurdly small; but they were a great advance upon nothing at all.

Early in the history of the English in India the Company found it necessary to provide hospitals for their servants and other Europeans in the Presidency towns. Madras was the first, about 1664. Bombay followed suit, in 1670, and Calcutta in 1707. These hospitals, however, were for Europeans only, and practically for Government servants only, for the soldiers and sailors, who provided the majority of the patients, were all servants of Government. For the general public—for the Indian population—there was no medical provision at all. And when such provision was made it was chiefly due to members of the I.M.S. The first suggestion of a hospital for the Indian public seemed to have been made by Surgeon William Gordon of Madras, in 1787. There was no provision for the treatment of the Indian population in the *mofussil* before the nineteenth century. There were hospitals for the army—general hospitals at the headquarters of divisions and brigades; regimental hospitals in the smaller cantonments—where the soldiers received medical treatment fairly up to the standard of the time. But these hospitals were for soldiers only. The first native hospitals in the *mofussil* were opened about 1804, at Dakka, Patna, Benares, and Murshidabad. But most of the hospitals and dispensaries in civil stations were started in the thirties and forties of the last century; the majority owed their origin to the energy of individual civil surgeons, who gave their time, their skill, and their money to found hospitals in their stations, collected subscriptions and got grants of public money to maintain these hospitals, and also themselves trained the necessary assistants, native doctors and compounders. The Calcutta Medical College was founded in 1835, and opened in that year with eight young Hindus as first-year students. They must have been courageous youths, these eight. Not only was the handling of dead bodies, in dissection, clean against the principles of their caste, but what must have been the condition of the bodies provided for dissection!

Medicine, surgery, sanitation, medical education, medical research, might all be considered as regular professional duties—all in the day's work for a medical officer. Most of the work done in natural science in India has been done by members of the I.M.S. To mention only a few names—in botany, Roxburgh, Wallich, and, in our own days, King and Prain; in geology, Falconer; in zoology, Alcock. Even the natural sciences were, until the specialization of the last half-century, part of the regular work of medical men. But members of the I.M.S. had gone far beyond the limits of regular professional work, and had had a large part in organizing and developing these great auxiliary services which now shared in the administration of India. Alexander Gibson of Bombay and Hugh Cleghorn of Madras were two of the first conservators of forests. James Ranken and George Paton were among the first postmasters-general. And the electric telegraph was introduced into India, and put into working order, by Sir William O'Shaughnessy-Brooke of Calcutta. It was unlikely that the I.M.S. would ever again furnish the British Foreign Office with an ambassador, or that it would again provide a Governor for Bengal; but the path of scientific research remained open.

In proposing the toast of "The Chairman," Sir LEONARD ROGERS said he supposed that most of the senior officers, at any rate, were of the opinion that the chief glory of the Indian Medical Service lay in the past, so it was appropriate that their chairman should be the historian of the service. However, he himself was not one of the pessimists who thought there was no future for the I.M.S., and he wished to take this opportunity of pointing out that under the reorganization scheme sanctioned last year the I.M.S. had obtained most solid advantages, which placed it in a more favourable position than any other service in India. Thanks to the necessity of providing a military reserve, which could not be altered without the sanction of the British War Office, the I.M.S. was now guaranteed the all-essential framework of two-thirds British officers in both the military and civil departments, against a maximum of 50 per cent. in any other service. In saying this, the last thing he wished to do was to disparage in any way the Indian members of the I.M.S., for he maintained that they were also recruiting the pick of the younger Indian medical men, many of whom had taken British qualifications, and thus had had the opportunity to absorb something of the spirit of the British race and of British medicine. Moreover, the pay of junior officers was now just three times the old rate, and that, too, with the sterling value of the rupee nearly 50 per cent. over that of his early days in India, with the additional advantages of study leave, passages for officers and their families, and better conditions of work for the military side in well-equipped station hospitals, in the closest harmony with the officers of the R.A.M.C. Another concession of vital importance, the necessity for which he had urged before the Lovett Committee some years ago, was the right of retirement after six years' service, with a gratuity of £1,000, and after twelve years with £2,500, to enable any officer dissatisfied with his service prospects to buy a practice at home. This concession also allowed the popularity or otherwise of the service to be gauged. Out of about a score of officers who might have retired with the first bonus last year the only one who availed himself of the opportunity was a man who was allowed to take it as an act of grace; so these officers, who should best know where the shoe pinched, were clearly satisfied with their prospects. Turning to the civil side, the position last year was not so satisfactory in two respects, but thanks to the help of their old friends in the British Medical Association the Naval and Military Committee had once more come to their help, with the result that two all-important concessions would be announced in the *British Medical Journal* and in India in a few days' time.* After explaining the significance of these concessions, Sir Leonard Rogers turned to the subject of his toast, describing the chairman, Colonel Crawford, as "the erudite historian of our service, who devoted thirty years' labour among the dusty papers of the record departments in Calcutta and at the India Office to collecting the mass of facts regarding the early history of the medical services in India with which every one of the 1,064 pages of his monumental work bristles." When the service lost a great administrator it gained a unique historian, for Colonel Crawford had continued to devote many years of a well-earned rest to his studies on the history of the I.M.S.

The following is a list of the officers present at the dinner:

Major-Generals: A. A. Gibbs, K.H.P., G. F. A. Harris, C.S.I., A. Hewson, C.I.E., Sir Leonard Rogers, C.I.E., F.R.S.

Colonels: J. Anderson, C.I.E., R. F. Baird, C. M. Goodbody, C.I.E., D.S.O., T. A. Granger, C.M.G., C. R. M. Green, G. Hutcheson, J. J. Pratt, F. Wall, C.M.G., C. N. C. Wimberley, C.M.G.

Lieut.-Colonels: A. Alcock, C.I.E., F.R.S., W. G. P. Alpin, O.B.E., G. T. Birdwood, E. W. Bradfield, O.B.E., Harold E. Brown, J. T. Calvert, C.I.E., D. Coutts, J. M. Crawford, O.B.E., C. D. Dawes, C. H. Fielding, H. E. B. Gibson, T. H. Gloster, H. Greany, D. Heron, C.I.E., E. V. Hugo, C.M.G., Dalzell J. B. Hunter, O.B.E., J. W. Illius, R. S. Kennedy, D.S.O., M.C., H. H. King, J. Kirkpatrick, J. C. G. Kunhardt, Clayton A. Lane, W. B. Lane, C.I.E., C.B.E., G. Rigby Lynn, D.S.O., A. A. Macnaught, F. O. N. Mell, C.I.E., A. Miller, T. R. Mulroney, J. H. Murray, C.I.E., B. E. M. Newland, E. S. Phipson, D.S.O., E. Rost, O.B.E., A. J. H. Russell, C.B.E., R. B. Seymour Sewell, W. S. Jagoe Shaw, N. S. Simpson, G. M. C. Smith, C.M.G., R. Steen, Ashton Street, W. A. Sykes, D.S.O., C. Thomson, G. Sloane Thomson, W. H. Thornhill, E. L. Ward, C.B.E., W. L. Watson, O.B.E., A. C. Younan.

Majors: T. J. Anderson, M.C., H. Chand, M.C., J. C. Chukerbuti, G. Covell, W. E. R. Dimond, Sir T. Carey Evans, M.C., A. H. Harty, L. M. R. Hennessey, W. P. Hogg, M.C., R. N. Kapadia, M.C., J. G. McCann, A. N. Palit, B. Prasad, W. C. Spackman, H. J. H. Symons, M.C.

Captains: J. H. Barret, Thaw Ba, A. T. Cox, T. J. Davidson, D. A. S. Hart, A. V. Lopes, D. P. McDonald, A. Rosenblum, A. N. Sharma, D. K. Thapar.

Lieutenants: H. J. Boulkley, T. W. H. Caughey, A. M. Fraser, F. T. Harrington, W. P. Lappin, P. Shannon, D. L. Trant, H. S. Waters.

* See Supplementary Report of Council, *Supplement*, p. 253.

DEATHS IN THE SERVICES.

Deputy Inspector-General Edward Julian Sharood, R.N. (ret.), died at Worthing on June 3rd, aged 80. He was educated at University College, London, taking the M.R.C.S. in 1860, and at Edinburgh University, where he graduated as M.D. in 1862. Entering the navy soon after, he attained the rank of fleet surgeon on June 16th, 1883, and retired with an honorary step of rank as D.I.G. on June 25th, 1893. He was in receipt of a Greenwich Hospital pension for good service.

First-class Assistant Surgeon Joseph Reginald Herbert Cabral, Indian Medical Department, was murdered by a Waziri fanatic at Bibizai, in Waziristan, on the North-West Frontier of India, on June 13th, along with another officer. Both were shot while travelling in a motor car. Cabral was born on May 9th, 1884, and entered the I.M.D. on March 31st, 1905, reaching his late rank in 1922. He served in South Persia during the great war.

Medico-Legal.

CHARGE OF PROFESSIONAL NEGLIGENCE.

SHEWRY *v.* MAYBURY.

BEFORE the Lord Chief Justice (Lord Hewart) and a special jury the hearing was begun on June 11th, and lasted seven days, of a case in which Leslie Shewry of Eastney, Portsmouth, an infant suing through his father, claimed damages against Dr. Lysander Maybury of Southsea for personal injuries owing to negligence in treatment, a charge which was denied.

Case for the Plaintiff.

Mr. Raynor Goddard, K.C., in opening the case, stated that when the boy Shewry was 14 days old, in August, 1920, Dr. Maybury, on the ground that he had congenital syphilis—from which, in fact, he had never suffered—injected into his head the arsenical preparation known as novar-enobillon. The fluid entered the tissues of the brain, destroying and injuring certain of them, so that the child was, and always would be, a hopeless idiot and epileptic. Dr. Maybury had attended at the birth of the child, and had attended the mother before that event. The injections were given at the surgery, and it was alleged that no blood test was made beforehand. Within an hour of the first injection the child had a fit. Four further injections were given on later dates up to September. Dr. Maybury never mentioned his suspicion of syphilis to the parents, and they believed that the injections had been given for an attack of jaundice from which the child had suffered. It was strongly denied that either of the parents had ever had syphilitic infection, and since the birth of this child, who was the first-born, they had had two perfectly healthy children.

Inspector Shewry of the Portsmouth police, the father of the child, testified to having paid more than £40 on account of Dr. Maybury's bill; the bills as presented amounted to about £142 altogether. Mrs. Shewry, in evidence, said that the doctor told her he would like to inject something to clear up the jaundice. He never inquired about her personal history or that of her family. The baby was not ill until the injections were given.

Dr. C. R. Crawford of Southsea said that he first saw the child in March, 1922, and thought the case to be one of epilepsy following injury to the brain. He would most certainly not feel justified in injecting "N.A.B." into the longitudinal sinus of an infant unless he had a positive result from the blood test. Nor did he think that a general practitioner would do the operation, which was one of great difficulty. Mr. Harold Burrows, F.R.C.S., until recently of Portsmouth, said that he had examined the child, and considered that the attempt to make such injections could have caused the injury. He would not agree that this was an ordinary case of idiocy due to some ante-natal cause, and he did not believe that Dr. Maybury ever saw in this child the stigmata of syphilis. Dr. W. B. Cosens of Chelsea said that from his recent examination of the child he had come to the conclusion that he was suffering from a condition which came on after birth. The operation performed in this case had now fallen into disrepute because of the possibility of a mistake being made. In his belief it was quite wrong to treat a child of 14 days with arsenic.

Case for the Defence.

Mr. Roland Oliver, K.C., instructed by Messrs. Hempsons for the defence, said that Dr. Maybury was being called to account for something he had done nine years previously. It was now the

to say that he had performed an operation known to be dangerous. The textbooks of that day had advocated injection into the sinus vein as the best, easiest, and safest way of introducing medicinal matter into a child's system. Dr. Maybury had performed the operation many times with perfect success. He would call a body of testimony to show that, as far as anyone could diagnose the case at all, it was one of ordinary congenital disease. The child, according to Dr. Maybury, was sickly from birth, feeble, constantly crying, developed "snuffles" and a characteristic rash, and had jaundice. For nearly a year after the injections the mother did not take the child to a doctor. The story of the convulsions had been antedated to implicate Dr. Maybury.

Dr. Maybury, who said that he was registered in 1879, bore out his counsel's statement, and added that previous to July, 1928, no one had accused him of treating the child improperly. In cross-examination, he admitted that an action for negligence was brought against him at Winchester assizes in 1925, and resulted in a verdict for the plaintiff, with £1,000 damages.[1] With regard to the present case, he admitted that his diagnosis of syphilis might have been wrong, but he saw signs of the disease, and had to treat it by the most approved method. He booked fees of five guineas for each injection, which he thought a fair charge. Asked about the effect on the brain should there be an accident in giving the injection, he said that some inflammation would be set up, but he did not think there would be destruction of brain tissue.

Evidence was given by Dr. W. F. Eberlie, now of Luton, who at the time was Dr. Maybury's assistant. He stated that cases of congenital syphilis in infants were frequently treated by Dr. Maybury by the injection of "N.A.B.," and he could not remember any case in which the injection was followed by fits or convulsions. It did not strike him that it was very early to operate on a child. Dr. R. C. MacPherson, medical superintendent of St. Mary's Hospital, Portsmouth, of which the child is an inmate, said that there was nothing to differentiate the case of Leslie Shewry, an imbecile, from scores of other cases. Since he first saw him, in May, 1926, his condition had become progressively worse. He had never seen or heard of a case in which these or similar results had been produced by an "N.A.B." injection. Dr. F. M. R. Walshe of Portland Place, a specialist in neurology, attributed the disease from which the child suffered to an imperfectly developed brain. To discover by percussion of the skull, as one of the expert witnesses said he had done, that the lesion in the child's brain was artificially produced and not congenital, was magic, not medicine. It was almost a typical case of Little's disease. Dr. George Riddoch, consulting neurologist, said that he examined Leslie Shewry in April, 1924. The child unquestionably had a lesion of the brain in both hemispheres. He did not believe that the condition was due to the effect of the injections. Dr. J. J. Abraham of Harley Street, a specialist in venereal disease, said that in 1920 an injection of "N.A.B." into the longitudinal sinus was considered the best method of treating congenital syphilis in the infant. He had himself treated 100 to 150 children by this method without any ill result. Even if Dr. Maybury's diagnosis was faulty, the treatment would do the child no harm. He agreed, in cross-examination, that if a doctor really diagnosed congenital syphilis he should inform the nurse or midwife that the case might be contagious. Mr. A. Lawrence Abel, F.R.C.S., of Harley Street, said that both in 1920 and at the present day the best way of treating congenital syphilis was by the injection of "N.A.B." into the longitudinal sinus; he had never heard of a case in which untoward results had followed. He considered that Leslie Shewry, whom he had examined a few months previously, had severe, but typical, Little's disease. Dr. A. Mearns Fraser, M.O.H., Portsmouth, said that the authorities had supplied "N.A.B." since 1917 to doctors who were regarded as capable of administering it properly, and Dr. Maybury, who had the necessary qualifications, was one of the first to whom the preparation was supplied.

The Summing-up.

After counsel had addressed the jury,

The Lord Chief Justice, in his summing-up, which lasted two hours, said that this was a case of exceptional gravity. He had had to do with no graver case during the twenty-seven years he had been engaged in the practice of the law, either at the bar or on the bench. The case was grave enough, in all conscience, when it started, but it had assumed an aspect of gravity which no one could have anticipated on reading the pleadings. Since the action came into court a great deal had happened. The writ was endorsed "for the defendant's negligence," and it was on the ground of negligence that the claim for damages was made. But in the course of the case the suggestion had been made on behalf of the plaintiff that this was not a case of negligence in treatment; a new and terrible suggestion had been made, that this defendant never diagnosed congenital syphilis at all, and entered upon a series of operations described as hazardous or dangerous deliberately in order to put fees into his pocket. If a doctor were guilty of that conduct it would not be a case of negligence, but of crime; not that he had exercised too little care, but that he had committed an assault, and also that he had attempted to obtain money by false pretences. If such a charge were seriously brought, the defendant would be in the dock, and the judge would tell the jury that they could not find him guilty unless they were satisfied beyond reasonable doubt. Imagine a prosecution attempting, after a lapse of nine years, on the basis of the controversial recollections of 1920, to secure the conviction of this practitioner. But had that course been taken, no mention of the case at Winchester would have been allowed to influence the verdict. It would have been far better, in this civil case, and after this lapse of time, had those responsible for the conduct of the plaintiff's case said, "Let us not disturb the calm atmosphere of this scientific inquiry by any topic of prejudice. Let us be fair with regard to the question of fees and other collateral matters which do not bear upon the scientific inquiry." Had that course been taken? No; the case began with talk about fees, it ended with talk about fees. He asked the jury to bring their minds dispassionately to bear upon what was really a scientific inquiry. Compassion for the child and its parents must not be allowed to divert the judgement. It must not be said, "This thing has happened; the injections were made; blame the doctor."

Again, under the system of law, which was the growth of many centuries, there were certain things called statutes of limitations. An action could not be brought for the recovery of a simple debt after six years, and in the case of things like assault the limitations were closer. Actions for assault and trespass, according to a statute of James I, must be commenced within four years of the cause of such action. If what was alleged in this case had happened to an adult, this action, relating to what had taken place nine years ago, could not have been brought, but the statute did not hold good in the case of an infant. Why did our wise forefathers pass statutes of limitations? No doubt in part it was to prevent or diminish fraud; but was it not, in addition, out of a sense of fairness, that it was not possible after many years fairly to bring to light all the relevant materials in a condition in which they might be suitably marshalled and impartially examined? He had been asking himself as the case proceeded, "What were *you* doing on a given date in 1920?" How impossible it was to recollect! And this case depended not only upon recollection, but upon controversial recollection—recollection developed, perhaps, during months and years of disappointment and resentment.

It was vital for the plaintiff to establish that the injuries complained of were the result of the negligence. It was idle to prove that the defendant was negligent if it was not proved that the negligence resulted in the injuries of which complaint was made. Otherwise it was like pulling a bell-handle with no bell at the other end. The case failed utterly unless it was shown that the bodily and mental condition of this child was the result of negligence or, as the case had developed, the calculated dishonesty of the defendant. There was no more room in this case for adjective or rhetoric than in an inquiry as to whether the formula for water was H_2O. The investigation was just as dry and scientific as that. Here was a boy in a certain condition of mind and body. Was it established that the cause of that condition was what was done by this defendant in July and August, 1920?

Lord Hewart then turned to the evidence. On the side of the plaintiff there was the evidence of Dr. Crawford, who, however, knew of no case in which an injection into the brain had caused epilepsy. Then came Mr. Burrows, who had been closely associated with this case, but who said frankly that he did not treat syphilis himself, and that, "except in textbooks," he had never heard of such a condition as was found in this case as being due to injection. When asked what the textbooks were, he said that Professor Leonard Findlay, in his book *Syphilis in Childhood* (1919), had referred to the danger; but it proved that Professor Findlay was speaking of the injection of salvarsan —"606"—which was a far more irritant thing, according to all the evidence. Mr. Burrows laid stress upon the coincidence of time—which, however, depended upon what was told him about the history—and upon the coincidence of place—that is, that the part of the brain which the injections presumably entered was the part affected in this case as judged by the paralysis. Finally, came Dr. Cosens, who had never seen the child until a few weeks ago, when the contest had already been marked out and the allegations put forward. He also said, however, that "N.A.B." was the best form of arsenic to use for intravenous injection; salvarsan was a more irritating form. But he believed that if "N.A.B." reached the brain cells it would destroy them.

What of the expert evidence on the other side? Gentlemen of high position in the profession had come into court to tell their experience. Dr. MacPherson had said that not only were the injections not the cause of the condition, but he could tell the court what the cause was: it was not the case that brain substance which had been there was destroyed by the mechanical introduction of a foreign body, but it was because, in the

[1] *British Medical Journal*, ii, 1925, p. 42.

inscrutable course of nature, this child had not been born with a complete brain; there had been failure of a part of the brain to come to birth. Dr. MacPherson said that the use of "N.A.B." injections in the longitudinal sinus was considered proper in 1920, and was considered proper still. Then came Dr. Walshe, who found that it was a characteristic and severe case of Little's disease, in which the symptoms were a generalized rigidity of the child's muscles, having the effect of partly paralysing its movements, and there were also indications of idiocy. Dr. Walshe knew of no case where such a condition as was found here was traceable to injections. This child's brain was very profoundly affected throughout its substance. If this amount of damage had been inflicted by outside interference the child must have died almost at once. Then came Dr. Riddoch, not originally anticipated as a witness, but called because of an incidental reference to a document made in the course of the case. He spoke to having seen the child in 1924, and said, "I never thought, nor do I think, that the condition was or could be produced by the injection of 'N.A.B.'" Then Dr. Abraham, surgeon to the London Lock Hospital, who said that in 1920 the method of "N.A.B." injection into the longitudinal sinus was considered the best and a safe method in treating little children. Finally, there was Mr. Abel, who said that the dose given to this child was only one-ninetieth of the dose given to an adult, and that if the fluid went through the sinus to the brain in this strength and quantity it would have no effect in ninety-nine cases out of a hundred, and he could not believe that in any case permanent injury to the brain could be caused. Such a portion of the brain could not have been damaged by external influence except by such injury as would kill.

Here was a body of testimony, said the Lord Chief Justice, from the heads of the profession that the injury could not have been due to the treatment. Were the jury going to say that they did not care whether it was impossible or not, that it might be quite true there had never been another case, but nevertheless they were going to find that it happened in this one? Unless the jury were satisfied that the condition of the infant was indeed due to the action of this doctor in 1920 there was nothing else in the case. Therefore he asked the jury to say, "Was the condition of this infant caused by the treatment administered by the defendant?" If the jury answered "No," he need not trouble them with anything else. If, however, it was found, somehow, that this deplorable condition of the child was due to these injections, one came back to the question of negligence. Here he quoted Mr. Justice Tindal in 1838—what he said then was still the law—and, earlier still, Lord Ellenborough. Every person who entered into a learned profession undertook to bring to the exercise of it a reasonable degree of care and skill. He did not undertake, if he was an attorney, that he would gain his case, nor, if he was a surgeon, that he would perform a cure, but he undertook to bring to the case a fair, reasonable, and competent degree of skill. A surgeon, to quote Tindal, did not become an actual insurer. He was bound only to display sufficient skill and knowledge of his profession.

The Lord Chief Justice then examined other points in the evidence in which there was conflicting testimony. In the statement of claim it was affirmed by the plaintiff that the child was suffering from thrush before the injections were begun; but in the witness-box, by the witnesses for the plaintiff, the question of thrush had been avoided, or negatived, or dated to the following month. Was it not apparent that for some reason or other, either deliberately or through the unconscious play of the mind, it had been thought desirable to exclude the mention of thrush, in a baby said to have been without spot or blemish, because with thrush there would be a rash? His lordship also referred to the fact that it was not until eighteen months after the birth that the father consulted Dr. Campbell about the child, and, after Dr. Campbell's death, Dr. Crawford. Was it to be believed that during that interval this child was having fits every day? How easy, looking back on the many occasions when this child was in the paroxysms of epilepsy, to antedate the beginning of the trouble!

The Jury's Decision.

The jury disagreed on the question whether the condition of the child was caused by Dr. Maybury's treatment. On the other questions which the Lord Chief Justice put to them they answered as follows:

> Did Dr. Maybury believe that the infant plaintiff had congenital syphilis?—Yes.
>
> Was Dr. Maybury negligent in diagnosing that the infant plaintiff was suffering from congenital syphilis?—Yes.
>
> Was he negligent in deciding on the method of treatment?—No.
>
> Was he negligent in the way in which he administered the treatment?—Yes, in his general treatment.

The Lord Chief Justice said that having regard to these answers the case was not closed; it would be put into the paper for further discussion by counsel at a date to suit both parties.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Assembly of New Parliament.

THE new Parliament assembled on June 25th, when the House of Commons re-elected Captain Fitzroy as its Speaker. The Lords took the Oath, and the Commons also spent the rest of the week in swearing in. The King's Speech is to be read by Royal Commission on July 2nd, and is expected to announce a long legislative programme, including proposals on health and housing. The medical M.P.'s and Peers will meet at an early date to set up a Parliamentary Medical Committee, and are expected to select a medical member of the Labour party as its chairman, to facilitate contact with the Government on medical subjects.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Rockefeller Fellowships for Medical Research.

THE Hon. Olive B. Buckley, B.M., Somerville College and King's College Hospital, and Miss Janet M. Vaughan, B.M., Somerville College and University College Hospital, have been appointed by the Medical Research Council to Rockefeller Travelling Fellowships for the year 1929-30.

UNIVERSITY OF CAMBRIDGE.

PROFESSOR H. R. DEAN, M.D., has been admitted as Master of Trinity Hall, in succession to Dr. Henry Bond.

The Council of the Senate has appointed Sir Humphry Rolleston, Regius Professor of Physic, to be a Governor of the Darwin Trust, which administers property at Girton for the encouragement of research into mental defect or disorder.

The Vice-Chancellor gives notice that a congregation, at which degrees in medicine and surgery will be conferred, will be held on Saturday, July 20th, at 2 p.m.

The following candidates have been approved at the examinations indicated:

M.CHIR.—J. Gray, R. H. Metcalfe.

THIRD M.B., B.CHIR.—*Part I, Surgery, Midwifery, and Gynæcology*: C. Arthur, A. R. Banham, D. W. Bawtree, G. H. Bradshaw, J. W. Bromley, G. Herbert, H. L. Hoffmann, F. W. Hollinworth, H. P. Hutchinson, R. W. McConnel, W. M. Macgregor, G. C. C. MacVicker, R. B. Mayfield, I. B. Morris, G. W. Pickering, P. H. L. Playfair, R. B. Pringle, B. Rothery, J. D. Simpson, F. J. G. Slater, J. H. Smith, E. C. Sugden, W. E. Tucker, J. K. Wilson-Pepper, W. R. Winterton, H. M. Yardley. *Women*: G. E. Grove, M. C. Seward. (*Part II, Principles and Practice of Physic, Pathology, and Pharmacology*): C. P. Campion, A. J. W. Channings, C. J. Grosch, C. Hill, T. A. A. Hunter, P. G. S. Kennedy, L. W. A. Lankester, J. F. V. Lart, G. E. Lewis, T. K. S. Lyle, F. H. McCay, R. A. Maynard, *A. D. Morton*, W. G. Oakley, J. R. Peacock, G. W. Bickering, L. J. Rae, T. S. Read, J. E. Semple, D. M. Stern, C. G. Townsend, W. E. Tucker, J. F. Varley, J. Vaughan-Bradley, F. W. J. Wood. *Women*: P. Ram, M. C. Seward, B. M. Williams, K. Wilson.

UNIVERSITY OF LONDON.

THE degree of D.Sc. in Anthropology has been conferred on William James Perry, University reader in cultural anthropology.

UNIVERSITY OF GLASGOW.

AT the graduation ceremony on June 19th (as recorded at p. 1175, the honorary degree of LL.D. was conferred upon Dr. C. O. Hawthorne, Chairman of the Representative Body of the British Medical Association.

The Harry Stewart Hutchison Prize of £55 for a writing or writings embodying original research in a branch of medical science relating to children was presented to Dr. Peter L. McKinlay for his essays on mortality of infants.

UNIVERSITY OF BELFAST.

PROFESSOR A. M. DRENNAN, M.D., F.R.C.P.Ed., has been appointed part-time lecturer in medical jurisprudence. Dr. C. S. Thomson, the new medical officer of health for Belfast, has been appointed part-time lecturer in public health administration.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—A. Campbell, R. Gilmore, S. R. G. Pimm.

MEDICINE.—P. S. Balachandran, G. A. F. Holloway, P. Horton, B. J. Niall.

FORENSIC MEDICINE.—A. Clark, H. G. Edmunds, B. J. Niall, Z. Risk.

MIDWIFERY.—L. P. Clarke, W. T. Ellis, J. Gordon, W. M. Hamer, J. H. Johnston, E. J. O'Loughlin, P. U. Rao.

The diploma of the Society has been granted to Mr. B. J. Niall.

Medical News.

THEIR Royal Highnesses the Duke and Duchess of York will open the Devonport Pathological Laboratory and the Devonport Nurses' Home, at the Dreadnought Hospital, Greenwich, on Monday, July 15th, at 3 o'clock.

THE annual dinner of the West London Medico-Chirurgical Society will be held at the Trocadero Restaurant on Thursday, July 4th, at 7.30 for 8 p.m.

FOUNDER'S DAY at Epsom College will be celebrated this year on Saturday, July 27th, when the prizes will be given away by Lord Eustace Percy, late President of the Board of Education, at 2.45 p.m. At noon there will be a service in chapel for boys and parents, and in the evening a performance by the School Dramatic Society.

A SPECIAL course in the radium treatment of cancer will be held at the Westminster Hospital Medical School from July 29th to August 3rd. The course is designed for medical men who have recently had, or are about to have, radium placed at their disposal. The fee is 10 guineas. Full information can be obtained from the Dean, 12, Caxton Street, S.W.1.

THE Fellowship of Medicine and Post-Graduate Medical Association has arranged two free clinical demonstrations: one on July 1st, at 4.30 p.m., at the West End Hospital for Nervous Diseases, by Dr. L. R. Yealland; the other on July 4th, at 3 p.m., at St. Paul's Hospital, by Mr. Winsbury White. From July 1st to 6th the following lecture-demonstrations will be given in connexion with "Baby Week"; this series is open to all members of the medical profession, and the fee is 10s. 6d.; July 1st, clinics at Queen Charlotte's Hospital, morning and afternoon, by Mr. Trevor Davies, Mr. Aleck Bourne, Mr. L. C. Rivett, and Mr. Leonard Phillips, followed by an evening lecture at the B.M.A. House by Dr. J. S. Fairbairn; July 5th, morning demonstration at the Tavistock Clinic by Dr. Hamilton Pearson and Dr. Alice Hutchison, and afternoon demonstration at the Infants Hospital by Dr. Eric Pritchard; July 6th, morning demonstrations at the London Lock Hospital by the obstetric surgeon and at St. Thomas's Hospital by Dr. R. C. Jewesbury. From July 8th to 20th there will be an afternoon course at the Hospital for Diseases of the Skin, Blackfriars Road; fee, £1 1s. In August three courses will be given: in urology at the All Saints Hospital for one month; in diseases of children at the Queen's Hospital for two weeks; and in medicine, surgery, and the specialties at the Queen Mary's Hospital, Stratford, for two weeks. Detailed syllabuses of courses and information on post-graduate work may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE following courses of lectures and demonstrations open to post-graduate students will be conducted in English at the Faculty of Medicine in Paris during October next: surgery of the eye, October 2nd to 12th: paediatrics, with special reference to respiratory diseases and tuberculosis in infancy and childhood, October 7th to 12th; diseases of the lung, October 21st to 26th; surgery of the digestive tract and liver, October 14th to 19th; cardiology, October 21st to 31st; and surgery of the ear, nose and throat, October 14th to 25th. Further information and particulars of fees, etc., may be obtained from the Association pour le Développement des Relations Médicales, Salle Béclard, Faculté de Médecine, Paris (6e).

A POST-GRADUATE course on recent advances in medicine, with special reference to therapeutics, will be held at the Faculty of Medicine, Vienna, from September 30th to October 13th, and followed by discussion classes from October 14th to 19th. Further particulars may be obtained from the Dean, Wiener medizinische Fakultät, Wien.

THE fortieth congress of the Royal Sanitary Institute will be held at Sheffield from July 13th to 20th, under the presidency of Earl Fitzwilliam. The details of the congress programme were published in our issue of May 25th (p. 971); it is now announced that the business will be divided into six sections—namely, preventive medicine, architecture and engineering, maternity and child welfare (including school hygiene), hygiene of food, hygiene in industry, and veterinary hygiene; and the following six conferences: representatives of sanitary authorities, national health insurance services, medical officers of health, engineers and surveyors, sanitary inspectors, and health visitors.

THE eleventh annual conference of the Association for Education in Industry and Commerce will be held in London on July 1st, 2nd, and 3rd, at the Savoy Hotel, Strand, and the Polytechnic, Regent Street.

THE sixth Congress of French-speaking Obstetricians and Gynaecologists will be held at Brussels from October 3rd to 5th, on the occasion of the fortieth anniversary of the foundation of the Belgian Society of Obstetrics and Gynaecology. The following subjects will be discussed: relations between the hypophysis and the genital system in women, introduced by Drs. L. Brouha of Liège and J. L. Wodon of Brussels; myomectomy during and apart from pregnancy, introduced by Drs. Mériel and Baillet of Toulouse and Brindeau of Paris; indications for, and technique of, sterilization in women, introduced by Drs. Muret of Lausanne and Laffont of Algiers. Further information can be obtained from the general secretary, Dr. Max Cheval, 16, Rue Alphonse-Holtat, Brussels.

THE eleventh Carlsbad international medical post-graduate course with special reference to balneology and balneotherapy will be held from September 15th to 21st. Clinicians and scientists from the medical faculties of nearly all European countries will give addresses. An invitation is extended to all physicians; those who accept will receive a passport visé without charge and a 33 per cent. reduction on all State railways in Czechoslovakia. A programme of entertainment has been arranged. Further information may be obtained from the secretary of the medical post-graduate course, Dr. Edgar Ganz, in Carlsbad, Czechoslovakia.

THE following German congresses will be held next September: Society of Tropical Medicine at Tübingen, 12th to 14th; Orthopaedic Congress at Münich, 16th to 18th; Industrial Hygiene at Heidelberg, 16th to 18th; Pharmaceutical Society at Münster, 25th.

THE friends, colleagues, and pupils of the late Professor J. A. Sicard have decided to have a medallion of him placed in the Hôpital Necker, where he held his consultations, and to raise a fund for investigations on the physiology, pathology, and treatment of the nervous system. Subscriptions should be sent to MM. Masson et Cie, 120, Boulevard St. Germain, Paris, VIe.

THE honorary degree of Doctor of Laws has been conferred by Princeton University, New Jersey, upon Sir Wilfred Grenfell, K.C.M.G., M.D.

PRESIDING over the proceedings of commemoration day at Livingstone College, Leyton, the Bishop of Chelmsford emphasized the importance of educating missionaries medically so that they might deal with the various emergencies in isolated parts of the mission field. Reports of the value of this training were given by missionaries from Sierra Leone and Paraguay. Mr. W. McAdam Eccles commented on the economical way in which the college was conducted, and pleaded for additional support. The principal of the college stated that twenty-four students had entered it during the present year, of whom eight had taken the full course. The number attending a course held last July was thirty-two, and twenty-four others had come for more elementary instruction as regards the care of the health.

Commonhealth, a periodical for the instruction of children in the prevention of tuberculosis, has been issued by the Tuberculosis Committee of the Belfast Corporation, under the editorship of Dr. Andrew Trimble, chief tuberculosis officer. Most of the articles in the April number contain information of interest to teachers, parents, and children alike. Copies may be obtained from Dr. Trimble at 1d. each, or 9d. per dozen, post free.

PART XIII of the Minutes of Evidence taken before the Royal Commission on Local Government has been issued (obtainable from H.M. Stationery Office or through any bookseller, price 6s. 6d. net). It contains the evidence given on behalf of the County Councils Association, the Association of Municipal Corporations, the Association of Local Government Officers, and by other witnesses between December, 1928, and March, 1929.

AT the last meeting of the Metropolitan Asylums Board it was reported that in the "Freedom from Accidents" competition for 1928 the National "Safety First" Association had awarded medals, or bars for medals previously awarded, to thirty-eight of the Board's motor ambulance drivers who had been free from accidents for from five to seven consecutive years. The medals were presented to the drivers by the chairman of the Board, Lord Donoraile. In addition, diplomas have been awarded to eighty-five other drivers who have been free from accidents for shorter periods. When regard is had to present-day conditions of traffic in the inner London areas in which most of the Board's ambulance work is carried out, and to the need for avoiding delay when en route, these figures may be regarded as very commendable.

CONSIDERABLE developments are foreshadowed at Woodhall Spa, where the baths were kept open through the winter for the first time last year. A proposal to enlarge the bath-house and to build a new hostel for patients to replace that burnt down a few years ago has been adopted by the controlling syndicate. The Alexandra Hospital (16 beds for men and

16 for women requiring spa treatment) is being enlarged and provided with a new heating plant, a room for Plombières douching, and another for electrical treatment.

DR. LUDVIG HEKTOEN, head of the department of pathology at the University of Chicago and director of the John McCormick Institute for Infectious Diseases, was recently decorated with the Norwegian Order of St. Olaf for distinguished service in medical science.

PROFESSOR KARL HERXHEIMER of Frankfort has been elected honorary member of the Dutch Dermatological Association, the Roumanian Dermatological Society, and the Dermatosyphilological Society of Saratow; and Professor Wilhelm Kolle has been nominated honorary member of the Società Italiana di Dermatologia e Sifilografia.

THE Hanover Medical Club, founded by the orthopaedic surgeon Georg Friedrich Louis Stromeyer, celebrated the centenary of its foundation last month.

THE following appointments have recently been made in foreign faculties of medicine: Professor Felix Klewitz of Königsberg, successor of the late Professor Eduard Müller in the chair of internal medicine at Marburg; Dr. Knoll of Arosa, professor of physical exercises at Hamburg; and Dr. R. Wagner, professor of physiology at Graz.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscia Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550. Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

GLAND IMPLANTATION FOR RHEUMATOID ARTHRITIS.

DR. WILLIAM ALLEN (Glasgow) writes: A Dr. Paul Niehaus of *Montreux claims to have cured some cases of rheumatoid* arthritis in women by the implantation of sheep's ovaries in the abdominal wall. I should be glad to know if any medical man in *this* country has had a patient treated by this method, or has actually seen a case of rheumatoid arthritis before and after this treatment, and what was the result?

STIES.

DR. J. E. HARFORD (Haxey, Lincs) writes: Could any reader give some suggestion for treatment of recurrent sties? The patient has had most of the ordinary treatments, including *x* rays to lids and examination for errors of refraction, of which there is none existing.

HAY FEVER.

DR. J. D. HINDLEY-SMITH (London, W.) writes: I should be grateful if anybody would inform me whether any clue is obtainable in a case of violent hay fever with the following history. The condition has in previous years begun about May 27th. This year has, botanically speaking, been a late year, and the hay fever did not begin until June 9th. Possibly this may suggest some particular variety of vegetable life to a reader having a better knowledge of botany than I possess.

SCREAMING FITS IN AN ADULT.

"SENEX" writes: I have a patient, aged 64, deaf, a professional man, with a large prostate, who has the usual disturbances every three hours at night. He had slight hemiplegia in 1927, was unconscious for two days, but completely recovered. He has suffered from muscular rheumatism since childhood, and now has rheumatic osteitis in the knees, but is able to get about for six-mile walks. He has lately developed frequent "startlings" during the day on slight noises, such as coal crackling in the grate. These starts are often accompanied by a loud scream. Valerian and bromide has no effect. These night and day disturbances are producing steady deterioration and depression. Suggestions for treatment and prognosis will be welcomed from any readers who have had similar cases under their care.

DIATHERMY OF THE TONSILS.

DR. WARNER COLLINS (London, S.W.), in reply to Dr. M. Y. Paget's inquiry (June 22nd, p. 1146) writes: I have treated over a hundred cases by diathermy within the last three years with no accident of any kind. Cocaine anaesthesia is used: there is no hospitalization of the patient, no shock, and no haemorrhage.

PAINFUL HELL.

"X. X." writes: In several recent issues you have published suggestions, in answer to a query by "GIZA" (May 11th, p. 890), on a case of painful heel. There have been various explanations of the cause of the condition, but I have not yet seen a reply by "GIZA" giving the final diagnosis. I feel sure that those who reply to queries, and no doubt others of your readers, would be interested to have the ultimate diagnosis, when this is available.

WATER SOFTENERS.

DR. W. A. D. LAWSON (Luton), in reply to "Member of Forty Years' Standing" (June 15th, p. 1104), writes: Having recently come to live in an area near London with a water of some 20 degrees of hardness (mostly temporary), I have installed a domestic softener costing £5 or £6. The apparatus is a cylinder some 6 inches in diameter and about 2 feet long, which connects like an ordinary hose-pipe to the kitchen tap. It is made by the Electrolux firm at Luton, Beds, and can effectually soften 15 to 20 gallons of water of above hardness. Larger forms are made which are fixed permanently to the pipes. After exhaustion renewal is brought about by passing through it a strong solution of salt. The same idea is used in the Permutit type of softener, and the chemistry is the exchange of calcium for sodium in the case of the carbonates, and on regeneration the sodium is retained and calcium chloride comes away. Hence there is nothing deleterious added to the water, and it is quite palatable, though some prefer the taste of hard water, and some think the latter makes better tea. Apart from the obvious advantages of soft water for washing, it is perhaps not so well known that soft water is better for most cooking purposes, especially of greens. One warning is, perhaps, worth while—namely, the softened water charged with soda should not be used in aluminium pans.

UMBILICAL DISCHARGE.

"CONSULTANT" writes in reply to "W. D." (June 15th, p. 1104), who asked if anyone could suggest the cause of an occasional discharge from the umbilicus in a woman of 32: I would suggest as the most probable cause a patent urachus, and that the fluid is *rather of the nature of urine mixed with some serum. I have* seen two cases in which the condition occurred as a complication of pregnancy. In one it never evidenced itself after the confinement, and in the other, in consequence of the discharge becoming somewhat worse after confinement, I cut down on the urachus and removed it. Both these cases were uncomplicated by any infection. In another case with definite abscess formation, shortly after confinement, I operated and removed a well-defined pus sac. The non-septic case showed quite clearly the communication between the bladder below and the umbilicus above. In the septic case, however, though I could trace a continuity between the lower portion of the abscess cavity and the bladder, I could not discover the connexion with the umbilicus. Ordinarily the urachus is cut off from the bladder by a valve-like arrangement, and, so long as this valve acts satisfactorily, there is no escape of urine into the urachus, which gradually shrivels and is converted into the cord-like structure, which one can easily recognize when opening the peritoneal cavity in the mid-line. Occasionally the action of the valve is incomplete and the urachus retains its patency so that any distension of the bladder may cause an overflow towards and an escape through the umbilicus. It is, then, quite possible that there may be merely an occasional escape of fluid from the umbilicus; or, with some obstruction at the vesical end, there may occur, if infection should gain entrance, a cystic enlargement, or, if it does, an abscess. "W. D." will find that there is a fairly large amount of literature on the subject.

INCOME TAX.

Sale of Practice on Introduction [illegible]

"R. J. F." has sold his practice as from August 19th, 1929, on a six weeks' introduction to September 30th, at the rate of £1,000 per annum, after which he hopes to go to another practice. How should his return for 1929–30 be made?

*** He will be liable for the period April 5th to September 30th at the amount of his earnings for that period and the Inland Revenue authorities are entitled to revise his assessment for the year ended April 5th, 1929, to the amount of his earnings for that year. After August 19th he will not be chargeable to any trade receipts for work done prior to that date, his general practice earnings having then ceased; except as regards the special fee of six weeks' salary at £1,000 per annum, which is more in the nature of remuneration for employment than of a share of practitioner. On the other hand, in dealing with the liability *on any new practice he may purchase he will not be allowed to*

adopt the cash basis, and will be chargeable on the basis of the value of his bookings. As regards the rendering of his return the most convenient course seems to be to explain the facts to the local inspector of taxes and arrange with him for the statement to be lodged after August 19th.

Cash Basis; Practice Sold.

"D. W. R." has relinquished his practice, and his accountant informs him that "he is liable for all fees received after relinquishing the practice, or, alternatively, that the assessor can go back and assess him on a credit basis."

*** The first alternative is not legally correct. As from the date "D. W. R." gave up the practice he ceased to derive *income* from it; any sum he may have received represented *payment of capital amount of debts* due to him as at the date of relinquishment. The second alternative, however, holds good, but it is very rarely applied, because over a period of, say, six years the annual value of the bookings is normally about equal to the cash receipts—in fact, if the bookings have been falling off the adjustment should work out to "D. W. R.'s" *advantage*. There is no special precedent or judicial decision on the point; in our experience it is admitted by the authorities.

New Partner: Succession or New Practice.

"PAR" has been taken into partnership by a practitioner who, up to then, had been in practice by himself. The inspector of taxes claims that the cash basis must be discarded and the practice assessed as a new one as from the date when our correspondent became a partner.

*** This involves the new legislation introduced by the Finance Act of 1926. As we read the relevant section the practice must be treated as a continuing one, unless both partners agree otherwise. *If so treated* there is no reason why the cash basis should be discarded, provided that *all* cash receipts are brought into the computation of the gross assessment, whether our correspondent is entitled to share in them or not.

Residence Abroad.

"R. B." inquires whether, if he lives out of Great Britain for more than six months in the year, he is entitled to claim relief in respect of income tax on his retired (naval) pay.

*** As a British subject living abroad he is entitled to a proportion of the personal allowance, according to the ratio of the amount of income assessable to British income tax to the amount of his total income, including therein, of course, income which may be exempt from assessment owing to his residence abroad.

Assistant: Board and Lodging.

"R. L." received as an assistant £300 a year *plus* free rooms and attendance. The inspector of taxes regards the latter benefit as worth £75 a year, and claims to assess "R. L." at £375.

*** One of the leading cases decided in the House of Lords many years ago that a bank manager was not liable to account for tax on the value of free accommodation, which he had no power to sublet, on the ground that that advantage of his employment was not capable of being converted by him into cash, though it saved him laying out some cash for his personal benefit. "R. L.'s" case seems clearly to fall within that rule, and it is not understood on what ground it is sought to assess him on the £75. We suggest that he should inform the inspector of taxes that he is advised that his case seems to be covered by the decision in the case of Tennant *v.* Smith, and should request the inspector to explain the grounds on which he seeks to differentiate that case from his own.

Earned Income Relief.

"H. W. H. H." has been allowed the one-sixth relief in respect of earned income as calculated on the gross earnings—£1,000, less expenses, £300. Is this basis correct?

*** Yes. The effect of the relief is to reduce the assessable earnings by one-sixth; £1,000−£300=£700 is the amount assessable, and one-sixth of £700 is the maximum amount of relief. The common sense of the rule will be apparent from the ordinary case of a tradesman whose gross profits may be three or four times his net profits, after deducting rent and rates, wages, and other expenses.

Employment: Broken Periods.

"A. R. B.'s" earnings during the income tax year 1927–28 were £167, partly as assistant and partly as locumtenent, but for six months of the year he was "virtually unemployed," owing to post-graduate work. For 1928–29 he earned £240 in a similar capacity. What is his liability for that year?

*** It appears from the facts that "A. R. B." ceased his employment in 1926–27, and started it again after completion of his post-graduate course. Section 45 (4) of the Finance Act provides that for the first year of the holding of a particular office or employment the amount to be assessed under Schedule E is the total earnings of that year. If our view is correct—that is, that the employment was temporarily discontinued—then 1928–29 is the first year of resumption, and "A. R. B." is assessable on the amount of the earnings of that year. We may, perhaps, add that a similar result would be reached if the professional work is regarded as producing profits assessable under Schedule D.

Motor Car Expenses.

"E. F. B." holds a public appointment and uses a car "partly for work and partly for pleasure," the total average mileage being about 7,000 a year. How should the claim to allowance for motor expenses be calculated?

*** The first essential is to ascertain approximately the ratio between professional and private use. Suppose it is half and half, then "E. F. B." will be entitled to one-half the depreciation allowance—which, on the basis of an original cost of £180, we calculate at one-half of £23 for the third year of the life of the car—*plus* one-half of the fixed charges—tax, insurance, and garage cost—and running expenses, petrol, oil, repairs, etc. When the car is replaced one-half of the obsolescence allowance should also be claimed as an expense.

Purchase of Motor Car.

"A. G." bought a new (first) motor car in February, 1928. What "expenses" can he claim, as against the year 1928?

*** No portion of the cash outlay on the purchase of a first car can be allowed, as it represents the investment of capital in the equipment of the practice; it may, of course, be different with a second car bought to maintain the equipment rather than to create or improve it. But "A. G." can claim as an "allowance," not strictly as an "expense," 15 per cent. or 20 per cent. of the cost, as representing depreciation, by reason of wear and tear.

LETTERS, NOTES, ETC.

LOOSE DIAGNOSIS OF DIABETES.

DR. F. G. BUSHNELL (Plymouth) writes: The tendency in certain quarters to diagnose diabetes on insufficient data is to be deprecated. If a patient's urine contains a small or large trace of sugar, without definite changes in his blood sugar, it is nowadays the fashion among certain physicians, though other characteristic diabetic symptoms may be absent, to diagnose diabetes and prescribe a restricted diet. Such traces of sugar in the urine may be temporary and be due to transitory ill health; thus a physician abroad diagnosed diabetes from the presence of sugar in the urine, though his diagnosis was promptly and rightly corrected by two London physicians. Something should be done to check this tendency to make a loose diagnosis of diabetes. The rigid dieting such diagnosis involves imposes a real and great hardship on working-class patients, and as a member of the British Medical Association for thirty-five years I ask the Association to take action.

MEDICAL GOLF.

THE Medical Golfing Society held their summer meeting at Walton Heath on Thursday, June 20th, by the kind permission of the Walton Heath Golf Club, and at the invitation of Lord Riddell, who again entertained all the competitors as his guests. A delightful day was spent, and the golf was distinctly good. Play was from all back tees. The results of the competitions were as follows:

Lancet Challenge Cup.—H. Gardiner Hill, 2 up. T. P. Kolesar all square.
Henry Morris Challenge Cup.—F. Rose, 2 up. R. Lindsay Rea, L. W. Bathurst, Sir Milsom Rees, A. Gallately, all 1 up.
Milsom Rees Challenge Cup.—F. Rose.
Veteran's Cup (presented by Sir Kenneth Goadby).—F. Rose.
Sealed Handicap (Mr. George Dawson's prize).—A. Soper, 1 up.
Class I.—First Prize: A. C. Palmer, 3 up. *Second Prize:* Sir Milsom Rees and A. Gallately, 1 up. T. P. Kolesar and D. Jackson, all square.
Best last nine holes; T. Stordy.
Class II.—First Prize: F. Rose, 2 up. R. Lindsay Rea and L. W. Bathurst, 1 up. J. Ligat, all square. *Best last nine holes:* W. Yorke-Davies, 1 up, after tie with L. W. Bathurst.
Foursomes.—C. Max Page and Sir Stanley Hewitt, 3 up. E. Lanning Evans and M. L. Trechman, 1 up.

HYGIENE FOR THE YOUNG.

WE have received from the Health and Cleanliness Council (5, Tavistock Square, W.C.1) a copy of its new publication, entitled *On the Arch of the Rainbow*, in which the author, Mary Tyreman, uses the pleasant form of the fairy tale to coat the pill of hygienic instruction. The booklet has been specially written for young people, and the Council is prepared to put supplies without charge at the disposal of teachers, Girl Guide captains, and all those interested in the teaching of hygiene to children.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 44, 45, 46, 47, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 283.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

610. B. abortus Infection in Man.

K. POPPE (*Münch. med. Woch.*, April 26th, 1929, p. 703) remarks that numerous instances of the occurrence of undulant fever in man due to *B. abortus* (Bang) have recently been recorded. The first cases were described in the United States, and subsequent cases were published in South Africa, the Dutch Indies, Spain, Italy, France, England, Switzerland, Holland, Poland, Sweden, and Denmark. The disease is most likely to attack persons engaged in farming who have to deal with living or slaughtered animals. The male sex is more affected than the female, and most infections occur between the ages of 15 and 40. The possibility of Bang infection should be remembered in the course of infectious diseases with prolonged fever and little disturbance of the general condition. It must therefore be considered in the diagnosis of typhoid, paratyphoid, influenza, malaria, and septicæmia, and in doubtful cases an agglutination test should be performed. Indeed, according to Poppe, in every case where the Widal test is required the agglutination reaction with *B. abortus* (Bang) should be tested. The relation of Bang infection to Malta fever and the question of identity of *B. abortus* (Bang) and *B. melitensis* (Bruce) are not yet settled.

611.

CHAMPNEYS (*Bull. Office Internat. d'Hyg. Publ.*, March, 1929, p. 423), after referring to investigations as to the occurrence of endemic undulant fever in Denmark, the United States, South Africa, Germany, France, and Italy, states that only 8 cases of endemic undulant fever of the Mediterranean type have been recorded in England (Manson-Bahr (2 cases), Byam (1 case), Box and Bamforth (1 case), Bamforth (2 cases), Woodley (2 cases). No statistics are available as to the frequency of infectious abortion in cattle in England, but it is considered probable that about 50 per cent. of cows supplying milk in this country are more or less affected. Among 158 examinations of blood made in North Ireland in 1927 a positive reaction was obtained in 39 cases (24.7 per cent.). In view of our ignorance as to the frequency in England and Wales of infectious abortion in cattle, it is impossible to have any definite knowledge of the occurrence of human infection. It is doubtful, however, if there are many unrecognized cases of undulant fever in the country, especially as a large number of practitioners must have become familiar with the disease in the war; other forms of endemic fever are rare in England. Champneys adds, however, that the importance of an extensive inquiry should not be underestimated, since undulant fever is responsible for a considerable amount of illness and financial loss, although the actual mortality is very low.

612. Heart-block and Uraemia.

H. K. MOHLER (*Journ. Amer. Med. Assoc.*, March 2nd, 1929, p. 706) reports two cases illustrating the association between heart-block and uraemia. One patient was admitted to hospital for removal of a hypertrophied prostate. Previous to admission he was in fair health apart from the discomfort of regular catheterization, but there were arterio-sclerotic changes in the cardio-vascular system. Immediately after the operation the pulse rate fell from 70 to 36, but within twenty-four hours the rate rose to 70 a minute, the blood urea was 35.32 (16.66 on admission), and there were symptoms of complete heart-block, which were confirmed by the electrocardiograph. Measures to promote elimination were taken and the patient's physical condition improved daily until forty-one days after the operation, when it suddenly failed again, death ensuing from uraemia on the forty-seventh day after operation. The electro-cardiogram and pulse rate showed that rises in the non-protein nitrogen content of the blood were accompanied by slowing of the heart due to block. The heart-block changed to normal rhythm with the return toward normal of the non-protein nitrogen. In the second case, a patient who had bradycardia, it was concluded that heart-block had been present for at least thirty years. This patient passed safely through an attack of uraemia without any changes in the heart and without symptoms of impairment of cardiac function. Complete heart-block continued after recovery from uraemia. The patient was able to return to work, and died three years later from cancer of the bowel. The author comments on the importance of considering the condition of the heart muscle when attempting prognosis, since the outlook in heart-block is largely dependent on this.

613. Meningococcal Meningitis.

A. CARBONELL and E. L. COOK (*Military Surgeon*, January, 1929, p. 49) record an outbreak at Fort Slocum, New York, of 19 cases of meningococcal meningitis; 11 patients completely recovered, 6 became unfit for service (5 on account of nervous sequels and one on account of synovitis of the knee), and 2 died. The authors' conclusions are as follows. (1) Strict attention should be paid to the patient's nutritional state, and tube feeding should be instituted when sufficient calories are not being ingested voluntarily. Care should also be taken that a positive water balance is maintained, and that dehydration does not occur, by administration of glucose solution in preference to saline on account of the additional calories contained in it. (2) Combined intraspinous and intravenous treatment should be given at intervals of eight to twelve hours until at least four intravenous and 6 intraspinous injections have been administered. (3) If at the end of specific treatment for forty-eight hours there is no marked improvement, another commercial type of serum should be substituted; if this type proves ineffectual at the end of the second forty-eight-hour period it should be changed, and so on, until a suitable serum is found. (4) An attempt should be made when possible to obtain a culture from the initial spinal tapping to be used for agglutination purposes in case the selection of a suitable serum from a number of commercial types becomes necessary.

614. Cardiac Disorders due to Hyperthyroidism in the Aged.

ACCORDING to F. KASPAR (*Wien. klin. Woch.*, April 25th, 1929, p. 520) hyperthyreosis in the aged represents an attenuated form of hyperthyroidism. The thyroid symptoms are mild or may even be absent, but the cardiac symptoms (palpitations, dilatation of the left ventricle, and auricular fibrillation) are very prominent; this type of thyreosis is consequently often mistaken for a primary cardio-vascular affection. The myocardium is affected very early, therefore an operation on the thyroid gland, in order to prevent cardiac insufficiency, should not be long delayed. The operation is not considered dangerous, and the results, particularly with regard to the cardiac symptoms, are very good. Success depends on an extensive bilateral resection of the thyroid. Suitable preparation of the patient and care after the operation are very essential.

Surgery.

615. Thoracoplastic Operations for Pulmonary Tuberculosis.

J. GRAVESEN (*Nord. Med. Tidskrift*, April 27th, 1929, p. 266) summarizes the results achieved with thoracoplastic operations at Vejlefjord Sanatorium, Denmark, during the past twelve years. Up to March, 1928, 191 thoracoplastic operations had been performed, 9 of them for such non-tuberculous conditions as bronchiectasis, empyema, and gangrene of the lung. There were 13 operation deaths, an operation mortality of 7.1 per cent. The facts that the operation mortality for the first 100 cases was 9 per cent., and only 4.9 per cent. for the subsequent 82 cases, showed how the improvement in technique and the increased frequency with which partial operations were performed reduced the risk of operation fatalities. These were due in 3 cases to post-operative paresis of the heart, in 2 to aspiration pneumonia, in 2 to shock, and in one to each of the following causes: novocain-adrenaline poisoning, embolism of the pulmonary artery, post-operative empyema in a lacerated pleural cavity, tuberculous pneumonia in the other lung, sepsis of the operation wound, and tetanus. In 63.6 per cent. the patients were discharged from the sanatorium much improved (41) or improved (73). Of the 182 cases of pulmonary tuberculosis thus treated 3 were still undergoing treatment, and were therefore not included in the analysis. To ascertain the late results of this treatment the author investigated the subsequent fates of the 155 patients whose operations dated back more than two years—namely, before March, 1926. On March 1st, 1928, 37 were fully fit for ordinary work and 28 were fit for light work—a total of 42 per cent. Death from tuberculosis accounted for 74, or 47.7 per cent.; 4 had died from some other disease than tuberculosis and 4 from some unknown cause. There remained 8 patients still invalided by tuberculosis. The author concludes that without this treatment only 10 to 15 per cent. of the patients suited for a thoracoplastic operation can expect, under conservative treatment, to recover fitness for work.

616. Periurethral Phlegmon.

M. F. CAMPBELL (*Surg., Gynecol. and Obstet.*, March, 1929, p. 382) states that the so-called "urinary extravasation" is an extensive fulminating phlegmon originating in or about the urethra, and is usually accompanied by massive genital and perigenital gangrene. It claims a high mortality of 40 per cent.; its early diagnosis and prompt treatment is therefore of prime importance. For anatomical reasons, which are fully explained, periurethral phlegmon is peculiar to males, and it may be met with at any age, even in infancy. The lesion is always an infection, most often following pre-existing urethral disease, notably stricture, but it may be secondary to trauma. Bacteriologically, streptococci, staphylococci, *B. coli*, *B. perfringens*, and various anaerobes are most often etiologically connected with the condition. French observers maintain that the phlegmon is caused by bacteria only; that actual urinary extravasation does not exist; and that fluid in the tissues simulating urine is an acute inflammatory exudate. Most frequently urethral necrosis occurs with subsequent perforation at or proximal to a stricture at onset; the lesion is a cellulitis with extensive vascular thrombosis, resulting in early gangrene. The toxic symptoms of cellulitis are marked; great local tenderness and swelling, chills, and fever, succeeded by toxic mental confusion, often progressing to delirium and coma, are the outstanding symptoms. The onset is abrupt, and most often the lesion is heralded only by acute dysuria, immediately followed by swelling and the signs of phlegmon. The correct diagnosis is usually made by inspection. Extravasation must be distinguished from the massive oedema of cardio-nephropathy and cirrhosis; in these cases, oedema elsewhere, particularly of the lower extremities, is present. The treatment is surgical, radical, and an emergency measure; delay and meagre incisions are fatal. Free drainage must be afforded to the bladder and involved cutaneous tissues by means of very wide incisions. The preservation of free bladder drainage and an enormous fluid intake are the chief post-operative measures. When stricture has been found, periodic dilatation with sounds must be employed as the only effective prophylactic measure against future phlegmons.

617. Perinephric Abscess in Children.

M. D'ALESSANDRO (*La Pediatria*, April 1st, 1929, p. 385) reviews the literature relating to this rather rare disease in children, and states that it is usually unilateral and has no special sex incidence. It may be primary, occurring in association with general infections, or secondary, and due to traumatism or the spread of a local infection. In children the secondary form is rare. The organisms commonly found are staphylococci, *B. coli*, or streptococci. The condition usually begins gradually; fever is often the only symptom at the outset, pain and swelling appearing later. Pain occurs on movement or pressure, inducing some rigidity of the spine and scoliosis; if the abscess tracks towards the psoas the characteristic flexion of the thigh may develop. The abscess may be too deep for fluctuation to be detected. The track of the abscess depends on whether it is above, below, or in front of the kidney. Hydronephrosis and sarcoma may lead to mistakes in diagnosis. Very rarely the abscess may dry up; if it points it generally tends to track downwards. The prognosis is, on the whole, good if surgical treatment is early, and the patient usually recovers in one or two months.

618. Diaphragmatic Hernia.

G. L. CARRINGTON (*Annals of Surgery*, April, 1929, p. 512) describes diaphragmatic hernia as a protrusion of an abdominal viscus through the diaphragm into the thoracic cavity. It may be congenital, acquired, or traumatic, and the first two types usually involve a passage through the hiatus pleuroperitonealis, the dome of the diaphragm, the oesophageal hiatus, the foramen Morgagni, or through an embryonic fusion point of the diaphragm. Treatment must be operative, the abdomino-thoracic approach providing the best exposure and freedom of manipulation, especially in the case of a very large hernia. The division of the phrenic nerve in the neck or chest makes the operation easier by paralysis of the diaphragm, and gastric lavage before the operation decreases the chance of aspiration pneumonia. Carrington reports a case in which a preliminary extrapleural thoracoplasty was performed involving the lower chest on the affected side. The second stage, or repair operation, was conducted through a thoraco-abdominal incision. Sterile fluid collected in the left side of the thorax, but it became purulent after the patient contracted a septic sore throat. After nine months' treatment the empyema thoracis was cured without approximation of the visceral and parietal pleura resulting; the treatment adopted was the drainage of the chest and alternate daily irrigations with Dakin's solution and neutral acriflavine 1 in 2,000. Eleven months after the operation the patient was well and had gained 18 lb. in weight.

Therapeutics.

619. Prophylactic Physical Exercises in Bronchial Asthma.

E. SCHILCHER (*Med. Klinik*, March 8th, 1929, p. 387) points out that though there is a general agreement on the importance of allergens, as defined by Storm van Leeuwen and others, in the production of asthma, the fact that the sensitiveness of the allergen-sensitive patient is subject to considerable variations must not be overlooked. He has confirmed the experience of other workers that this predisposition to asthmatic attacks may be considerably diminished by such general methods of treatment as substituting a diet which is mainly vegetarian for one which is rich in fats and purins, and reducing the intake of sugar, vinegar, salts, and cold drinks. The following prophylactic measure, which he has found useful for some years in a large number of cases, was suggested by the fact that many asthmatics are free from attacks during the warm months of the year and in a warm climate. Profuse sweating is induced by physical exercise in a warm atmosphere several times a week. Patients in whom the heart has been little affected should engage in drill, gymnastics, or dancing, in a room which is as free from dust as possible and heated by steam radiators to a temperature of 30° C., though, when once an adequate secretion of sweat has started, the presence of a certain amount of dust has little effect on the patient. These exercises are repeated three to six times, and are then omitted for four to six weeks, during which time the patient generally remains free from attacks. Schilcher remarks that other methods of inducing sweating, such as hot-air baths and vapour baths, have proved much less effective in the treatment of asthma, since the muscular activity of the whole body has a beneficial effect on the circulation, metabolism, and respiration, which the other forms of treatment lack. For patients for whom indoor exercise such as that described is impracticable he suggests fairly brisk walking exercise on the level several times a week, preferably in the sunny hours in the middle of the day, and gymnastic exercises, mainly of the legs, in short spells for a total of forty minutes before going to bed. These facilitate the expectoration of tough accumulations of secretion and remove the residual air from the lungs, besides reducing the risk of gastro-intestinal distension from flatus.

620. Therapeutic Uses of Pepsin.

M. LOEPER (*Bull. de l'Acad. de Méd.*, séance, April 23rd, 1929, p. 510) believes that the activity of pepsin is not limited to the stomach, but that it has a general physiological action. Pepsin may be gastric in origin, but, according to the author, its diffusion throughout the body is a fact. It has been found in the cerebro-spinal fluid, and a ferment very similar to pepsin impregnates the pneumogastric of the dog during digestion. Part of the pepsin is reabsorbed in the stomach and part in the small intestine. Absorption depends on the permeability of the mucous membrane. Pepsinaemia, which is difficult to demonstrate, and pepsinuria, which appears one hour after food, result. Pepsin appears to be a hormone capable of influencing directly or indirectly the organs, tissues, and nervous elements. It can safely be given to man in hypodermic doses of 0.1, 0.2, and 0.4 gram without accident. It increases the peptic power of the gastric juice, the intensity and frequency of intestinal movements are augmented, and diarrhoea may be caused in constipated subjects. In its general action it gives rise to a hyperglycaemia, hinders the action of insulin, slows the pulse, and lowers arterial tension. A specific action on the vagus is shown. Peptone in identical doses and the same dilution does not produce the same results. Treatment by hypodermic injections of pepsin is recommended for conditions of hypopepsia, hypotonia, constipation, tachycardia, and vascular hypertension. Diabetics and patients with kidney disease are particularly sensitive, and the dosage for them should never exceed 0.2 gram. Loeper adds that pepsin injections also possess an anti-anaphylactic power; he has employed them in asthma, urticaria, and for patients sensitive to alimentary proteins. He considers it probable that there is a formation of "antipepsin" in the body.

621. Phenylhydrazine Hydrochloride in Polycythaemia Vera.

PHENYLHYDRAZINE hydrochloride is a popular therapeutic agent in the treatment of polycythaemia vera, but the fact that there is some risk entailed in its administration is pointed out by H. Z. GIFFIN and H. M. CONNER (*Journ. Amer. Med. Assoc.*, May 4th, 1929, p. 1505), who report a series of forty-one cases treated by them since 1924. There were very good results in twenty-five patients, who were relieved of symptoms and were enabled to resume whole- or part-time work, regulating

their own dosage subsequently according to their individual requirements. The dosage employed in the series started with 0.1 gram three times a day and rose to a total of 3.4 to 7.6 grams. Most of the patients in whom the results were favourable were protected from any recurrence of the symptoms by taking 0.1 to 0.3 gram each week, whenever the symptoms showed signs of returning. Of the remaining patients, eight did not regain good health owing to the disease being advanced and complicated by arterio-sclerosis. Ten patients died, one accidentally and one of pneumonia. As the result of their experience the authors consider that patients with advanced polycythaemia vera who are necessarily confined to bed should not receive this treatment; extreme care should be taken in giving the drug to patients over the age of 60, or who have marked arterio-sclerosis or advanced visceral impairments. No higher initial dose than 0.1 or 0.2 gram should be administered, and the effect of this must be watched over several succeeding days. Similar care should be taken in the case of patients who have probably had thrombosis, and every effort has to be made to keep the already sluggish circulation in this disease as free as possible; the patients are therefore encouraged to walk about freely and are given massage and exercises if in bed.

Neurology and Psychology.

622. Personality Changes following Cerebral Trauma.

J. KASANIN (*Journ. Nerv. and Mental Dis.*, April, 1929, p. 385), as the result of a systematic investigation of mentally defective children in a Boston institution, found that 10 per cent. of them, who had been originally diagnosed as psychopathic personalities, had received some injury to the brain during childhood or adolescence. The author remarks that in addition to the problem of the relation of cerebral injury to personality disorders the interesting point has been advanced by some authors whether the pathology of the central nervous system in cerebral trauma and epidemic encephalitis is essentially of the same character, and in this connexion he reviews the pathology of cerebral concussion in adults and children, and concludes that there is also a clinical similarity. The personal changes in the two conditions are somewhat of the same type—namely, extreme emotional instability, outbursts of temper, egocentricity, and inability to follow a definite goal in life. Such a parallel ends with the prognosis. As seen in Kasanin's cases, there is, in spite of a long period of various conduct disorders, a tendency towards adjustment on a somewhat lower level, while patients suffering from sequels of epidemic encephalitis show a grave prognosis. Brain injury and encephalitis as such do not cause a specific reaction as far as behaviour is concerned, and any factor which causes a diffuse process in the central nervous system will interfere with the formation of proper inhibitory influences. Cases of personality changes require careful history probing, especially with regard to early encephalitis or brain injuries; when there has been a history of injury a very thorough neurological examination is essential. Certain phenomena associated with post-traumatic states are of diagnostic importance. Encephalography by the lumbar route should be freely employed. Any organic treatment is impossible, and these patients must therefore be treated by environmental change and psychotherapy. Special training in a correctional institution may be necessary in some cases. As a prophylactic measure the child should be taken to the country shortly after the injury in order to avoid city excitement and stimulation. Fifteen cases of personality disorders are reported, all of which were treated first as functional cases with extensive psychotherapy and exploration and change of environment, and only after repeated failure of the treatment was it felt that they were personality disorders of definite organic etiology in which psychotherapy had only a limited application.

623. The Treatment of Epilepsy.

SINCE there has lately been a tendency to develop some definite conception of the perverted physiology of epilepsy and to design treatment accordingly, I. ATKIN (*Journ. Mental Sci.*, January, 1929, p. 101) briefly reviews several forms of therapy, with the theories on which each is based. In support of the vasomotor theory of causation is the known fact that sudden cessation of the cerebral circulation will cause epileptiform convulsions, and that vasomotor spasm may produce fits through cortical anaemia. On this hypothesis treatment with belladonna, nitro-glycerin, and amyl nitrite has been tried, excellent results with the last-named having been claimed by Popea and Eustatziou. This theory leaves several problems unanswered, and allergy and toxaemia have been advanced as possible causative factors. The allergic theory regards epilepsy as a manifestation of sensitization. This was suggested by the temporary disappearance of fits in cases treated with serum for some other disease and by the fact that occasionally fits seem to be caused by certain foods. Protein therapy has yielded success in the hands of some authorities, and either horse serum, peptone, or tuberculin may be used. The metabolic theory of Collier is based on the occurrence of fits in various diseases of the endocrine glands and of the renal and hepatic systems, in eclampsia, in lead, bismuth, or alcohol poisoning, and by the periodical tendency of fits. The actual metabolic toxin has not been determined with certainty, but ammonia, choline, bile sulphates, or uric acid have been suggested as such. Atkin has not found benefit from the use of potassium-boro-tartrate, recommended by Marie on the theory that the dyscrasia was due to a disturbed acid-base equilibrium of the blood. There is much evidence in favour of the psychogenic theory. A fit often improves the patient's condition, and the average epileptic possesses a peculiar mentality. Causal emotional factors may act through the autonomic nervous system in producing the seizures. As regards general treatment, Atkin states that there are many secondary causal factors in epilepsy. Emotional changes play an important part, and a thorough knowledge of the patient's temperament is a useful aid in treatment. Constipation is undesirable, and is better treated by diet than by indiscriminate purging. Dyspepsia, fatigue, excessive physical exertion, and atmospheric changes are causal factors; hence the importance of general hygienic measures. Judgement should be used in prescribing bromides, and the required dosage can only be discovered by trial. Luminal, though allowing compensatory irritative symptoms to develop, has been found useful in several established cases where bromides were not well tolerated.

624. Circumscribed Serous Spinal Meningitis.

UNDER certain pathological conditions, such as trauma and syphilis, membrane-like bands form between the arachnoid and pia, or portions of the latter become adherent to the arachnoid membrane, thus occluding whole sectors of the subarachnoid space. This interferes with the free circulation of the cerebro-spinal fluid, and many cases of so-called spastic paraplegia are believed to be due to these circumscribed accumulations of the fluid. G. B. HASSIN and E. ANDREWS (*Journ. Amer. Med. Assoc.*, March 16th, 1929, p. 877) report two cases of circumscribed serous spinal meningitis in females aged 14 and 29 respectively. In the first, the youngest case recorded, the condition was due to trauma, and in the latter to syphilis. In the traumatic case laminectomy effected a definite cure, while in the syphilitic one this operation, combined with specific treatment, was of no avail, and the patient eventually died. Trauma is said to be a less common cause than syphilis, and the latter affects the nervous system in various ways. The usual meningeal changes are adhesions and thickenings, which do not yield to the anti-syphilitic remedies usually so effective in other types of cerebro-spinal syphilis. There may be a great disparity between the clinical and pathological manifestations, and in such cases the disease is most likely to be found affecting the meningeal or epimeningeal spaces. The result of treatment in the two cases shows clearly the greater danger of the syphilitic type, in which the symptoms and sequels are treated, leaving the cause undisturbed; in the traumatic form the sequels only are dealt with. In obscure cases of spastic paraplegia in which primary cord lesions such as myelitis, syringomyelia, or multiple sclerosis can be excluded, laminectomy is indicated. This should also be resorted to in those cases of spastic paraplegia known as Erb's type of cerebro-spinal syphilis (syphilitic spastic spinal paralysis), combined with a vigorous antisyphilitic treatment.

625. Double Hysterical Amaurosis.

RENEDO (*La Med. Ibera*, March 9th, 1929, p. 311), who records an illustrative case, emphasizes the extraordinary rarity of double hysterical amaurosis in contrast with unilateral amaurosis, which is much less unusual, and more or less marked amblyopia of one or both eyes, which is much more frequent and easy to diagnose. Renedo's patient was a woman, aged 21, who suddenly became completely blind. Examination made the following day showed that the eyeball from cornea to retina was completely normal. Lesions of the optic nerves, chiasma, optic radiations, or occipital lobe were excluded by the absence of any other symptoms, such as paralysis or psychical changes. On the other hand the presence of hysteria was shown by anaesthesia of the palpebral conjunctiva, with conservation of corneal sensibility, lack of sensibility to contact and to sensations of heat, cold, and pain in the areas supplied by the first and second branches of the trigeminal nerve, anaesthesia of both forearms, feet, and soft palate. Complete recovery of vision followed the subcutaneous injection of sterile water first in the left and then in the right temporal region.

Obstetrics and Gynaecology.

626. Tuberculosis of the Cervix Uteri.

TUBERCULOSIS of the cervix uteri is very rare and fewer than twenty primary cases have been reported. Secondary involvement of the cervix is much more frequent. MARION DOUGLASS and M. RIDLON (*Surg., Gynecol. and Obstet.*, March, 1929, p. 408) report two cases, one of pantuberculosis of the pelvic viscera, and the other a presumable case of primary tuberculosis of the cervix, since there was no evidence of the disease in other organs. Complete recovery followed panhysterectomy in the first case. Vigorous antisyphilitic treatment was given in the second case, but this produced no improvement, and the patient refused operation. Tuberculosis of the cervix is due to either a blood stream infection or to an ascending infection from a primary genital lesion. Primary infection has been found in women whose husbands had phthisis, infection taking place both generally through tuberculous sputum and infection of hands, or by transmission of the bacilli from a tuberculous epididymitis. Anatomically the lesions have been classified as miliary, interstitial, papillary, and ulcerative. In early cases the lesion is usually hypertrophic, proliferative or vegetative; whereas in advanced stages true tubercle formation and ulceration with loss of tissue is a pronounced feature. The different anatomical forms are possibly varying stages of the same pathological process. The gross appearance is often confusing, and microscopic examination is necessary for correct diagnosis. Usually in tuberculosis the tissues tend to be softer than in carcinoma, and lack friability. The symptoms are highly variable and indefinite; malaise, occasionally fever, amenorrhoea, and leucorrhoea have been noted. Slight haemorrhage after coitus is common, but a blood-stained purulent discharge is a typical finding in contrast with the more watery discharge of cancer. The prognosis is good in primary cases, but in secondary ones it depends on the severity of the general infection. If the lesion is definitely primary, surgery is indicated, total abdominal hysterectomy being the method of choice. If the vagina is involved, its extirpation may be necessary. Amputation of the cervix is advised when a more radical operation is contraindicated. In secondary lesions only palliative remedies are advised. Cauterization may give some relief, and astringent douches may be useful. Radium may be used, but it is contraindicated if salpingitis is present. The general treatment of the patient is very important; primary cases should be dealt with promptly, as general systemic tuberculosis may ensue.

627. The Zondek-Aschheim Reaction in Pregnancy.

R. BRÜHL (*Deut. med. Woch.*, April 26th, 1929, p. 696) employed this test in 68 women at different periods of pregnancy; 2 were in the second month, the clinical diagnosis being inconclusive. Of these 68 patients, 67 gave positive reactions and one was negative in the fifth month. Furthermore, in six cases of tubal pregnancy the test was performed eight times, and all were positive. He obtained a positive reaction once in the urine of a woman six weeks after her confinement; also in an erosion of the os with leucorrhoea in a woman aged 37. The tests were positive also in three cases of colpitis (kraurosis), in four cases of climacteric disturbances, and in seven cases of carcinoma or sarcoma of the genital organs. Brühl concludes as follows: (1) A positive result of the Zondek-Aschheim reaction is a very conclusive indication of the existence of pregnancy, and a negative result excludes pregnancy with absolute certainty. (2) It is very probable that in the anterior lobe of the pituitary body at least two hormones are formed: one causes maturation of the follicle, and is found in the urine of women after the climacteric and after oöphorectomy, while the other influences the formation of the corpus luteum, and is chiefly demonstrable in pregnancy. (3) In the urine of gravid mares and cows the hormone could not be demonstrated.

628. Parturition and Infantile Albuminuria and Glycosuria.

K. JAROSCHKA (*Zentralbl. f. Gynäk.*, March 2nd, 1929, p. 522) comments on the many differences of opinion about the etiology of albuminuria, its frequency, time of appearance and duration, and its relation to the condition of the mother or the duration of labour. In forty newly born male children, watched carefully from birth until the sixth day, he found albumin in 65 per cent., the maximum amount occurring in those between 3 and 5 days old. After spontaneous delivery it was found in 50 per cent., and after operative delivery in 80 per cent. The length of the labour appeared, however, to make no appreciable difference. The worst case was the child of a woman in the pre-eclamptic state. Albumin was present in all the five forceps deliveries, the quantity varying with the difficulty of the case. On the whole a long labour with plenty of time for head moulding caused less albumin than a quick operative delivery with more sudden pressure on the head. Dehydration is said to be a contributory and sometimes the only cause of albuminuria; when there is much loss of fluid acetone bodies are also found. In four cases albuminuria was produced by applying a tight bandage round the kidney region, showing that purely mechanical pressure must be considered a possible cause. Glycosuria is said to be much rarer, and is practically unknown after spontaneous delivery, however long. It is occasionally found after operative intervention, especially when high forceps are used, and in cases where the carbon dioxide concentration has been increased; it is usually found in very large and heavy children.

Pathology.

629. The Survival Rate of Leucocytes in Disease.

R. LUSENA (*Il Policlinico*, Sez. Prat., April 8th, 1929, p. 479) has studied the duration of survival of leucocytes in relation to death of the individual with a view to determining whether the leucocytes were affected by important alterations in various organs, or whether they retained independent vitality. The author had previously found that in a case of chronic myeloid leukaemia there was a diminished vitality in the leucocytes, and that this diminution was enhanced immediately before the death of the patient. Excluding diseases of the haemopoietic system, the author investigated four cases. The method adopted was to dilute a sample of blood with sterile physiological solution, and to keep the sample thus diluted in the author's modification of Forti's pipette at a freezing temperature. A drop of the mixture was examined at intervals on a warm stage, and the time of cessation of motility of the leucocytes was noted. The remainder of the sample was inoculated in broth, and was found to be sterile in each case. The four cases studied were: (1) malignant tumour of the abdomen with cholaemia; (2) miliary tuberculosis; (3) poisoning with corrosive sublimate; and (4) diabetic coma. Two samples of blood were taken, one about a month before death and the second within a few days of death. The observations were as follows on both occasions: (1) there was no movement of leucocytes after fifteen hours; (2) leucocytes survived for five days; (3) leucocytes survived for fifteen days; (4) survived for eight days. The author concludes that the alteration in the survival rate is associated with the cause of death. As the survival rate was the same on both occasions in the same patient, apparently the leucocytes remained uninfluenced by the patient's general condition.

630. The Flocculation Reaction of Vernes in Osteo-articular Tuberculosis.

J. VALLS and V. C. GIRARDI (*Rev. Med. Latino-Americana*, February, 1929, p. 506) investigated the flocculation reaction of Vernes in 90 cases of osteo-articular tuberculosis and came to the following conclusions. The high percentage of positive results in patients with undoubted osteo-articular lesions justifies this reaction being considered as of diagnostic value. In incipient forms, or with small localized foci, the results are inconstant, and consequently of little value. The reaction is of great service in enabling one to appreciate the degree of improvement or aggravation, since the reaction closely corresponds to the evolution of the lesions.

631. Splenic Irradiation and Sedimentation of Blood Cells.

R. DE TULLIO (*Studium*, March 20th, 1929, p. 110) describes a series of investigations undertaken to show the effect of irradiation of the spleen on the velocity of sedimentation of the blood cells. Since the spleen is an organ intimately concerned with the composition of the blood, it was thought probable that by submitting it to *x*-ray irradiation an effect would be produced on the velocity of sedimentation. The subjects of the investigation were healthy individuals and patients suffering from splenomegaly—both the syphilitic and malarious forms. *X*-ray irradiation was applied to the splenic area once daily for three days. The velocity of sedimentation was studied immediately after the first treatment, and again six and twenty-four hours afterwards. The method of Westergreen was used, the blood being drawn from a vein and mixed with 5 per cent. sodium citrate. The reading of the sedimentation was taken at thirty, sixty, and ninety minutes, and two, three, six, and twenty-four hours. All the readings pointed to the same conclusion—namely, that from one to six hours after the irradiation there was a transient acceleration in the velocity of sedimentation; it was invariably followed by a retardation more marked than the preceding acceleration, so that on the whole the velocity was diminished.

IN TREATMENT OF DELAYED UNION OF FRACTURES

1. A fractured humerus showed no union after six and a half weeks. A daily injection (Ostelin Ampoules) was given for six days, and two at three-day intervals.

In eight days there was callus formation, and firm union within four weeks.

2. A fractured femur (lower third) in a man of 67 showed no heal ng after six weeks. The treatment was five injections at daily intervals, and three at two-day intervals, with "Ostelin" by mouth.

A considerable mass of callus was felt within 14 days and an excellent recovery was made.

OSTELIN AMPOULES

Each ampoule contains 1 c.c. of a sterile solution of "Ostelin" in olive oil, equivalent in vitamin D potency to 50 c.c. of cod-liver oil.

In boxes of 3 and 10.

For intramuscular injections: If given early three or four injections at two-day intervals should suffice

Also OSTELIN LIQUID : OSTELIN TABLETS : OSTELIN EMULSION : OSTOMALT.

Further information from
Glaxo Laboratories, 56, Osnaburgh Street, London, N.W.1.

NO FAT INTOLERANCE

Excess of fat in infant foods sets up varying degrees of fat intolerance and results in expulsion of valuable lime salts in "fatty stools."

Adding vitamin D to Sunshine Glaxo as a separate, non-fatty, and standardised concentrate has allowed the fat content of the food to be adjusted so that there is no risk of fat intolerance.

Balanced provision of fat, carbohydrate and protein—extra vitamin D to ensure full assimilation of lime—the composition of Sunshine Glaxo is as close to perfection as present-day knowledge allows.

SUNSHINE GLAXO

WITH ADDED VITAMIN D

PROVED MORE EFFICIENT THAN NICKEL-PLATED INSTRUMENTS

NOT once, but many times, Doniger Krome-Plate Instruments have proved their superiority in practical tests carried out in some of the most important hospitals and clinics of America.

The reason for this superiority is not far to seek. Doniger Instruments are made from high carbon steel of fine quality They are fashioned by master craftsmen and polished to the highest degree of smoothness. They are then nickel-plated, and finally given a heavy plating of pure chromium. This treatment makes Doniger Instruments—

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

These advantages make the use of Doniger Instruments a very real economy, especially so in conjunction with the fact that Doniger Instruments cost only a fraction more than nickel-plated Instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

All particulars may be obtained from the Resident Medical Superintendent,
Dr. MARY R. BARNES, M.D., D.P.M.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit *this branch for a short seaside change or for longer periods. The Hospital has its own private* bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. T.T. Langham 1103.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) C.M.EDINBURGH. M.C.CANTAB. F.R.C.S.EDINBURGH. M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

APPOINTMENT OF HONORARY SURGEON.

Applications are invited for the above appointment. Goculdas Tejpal Hospital (266 beds) is associated with the Grant Medical College, Bombay, for clinical teaching of undergraduates. The appointment carries an honorarium of Rs.150 per mensem, and will be for a period of five years, subject to termination by three months' notice on either side.

Applications, in duplicate, marked "Honorary Surgeon," stating age, qualifications, and experience, together with copies of three recent testimonials, must be sent so as to reach the undersigned not later than the first week in August.

F. N. MOOS, M.D.Lond.,
Superintendent, G. T. Hospital, Bombay.

The Urban District of Weston-SUPER-MARE.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Council invite applications for the position of Medical Officer of Health and Medical Superintendent of the Isolation Hospital.

For the present the appointment will be a part-time one, but it is hoped that further Public Health work will become available in the near future.

The gentleman appointed will be precluded from engaging in general practice, but will be given opportunity for doing other remunerative work.

Applicants must be registered Medical Practitioners, holding a qualification in Public Health or State Medicine. Previous experience in school medical work is desirable.

The appointment will be subject to the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926, and the duties will be those prescribed by the Order, and such other duties as are or may be imposed by the Council. Any other work or duty proposed to be undertaken to be subject to the approval of the Council.

Commencing salary £600 per annum, payable monthly.

Office accommodation and staff are provided by the Council.

The office is an established post under the Local Government and Other Officers Superannuation Act, 1922.

Personal canvassing of members of the Council, either directly or indirectly, will be a disqualification, but 24 copies of the application and testimonials may be sent to me for the use of the Council.

Applications, on forms to be obtained from the undersigned, endorsed "Medical Officer of Health," and accompanied by copies of three testimonials of recent date, must be forwarded to me before July 15th next.

SYDNEY C. SMITH,
Town Hall, Clerk to the Council.
Weston-super-Mare.

Applications, with one copy of testimonials, to be lodged with the Clerk to the Board not later than Saturday, July 13th.

Particulars of the appointment may be obtained on application to the Clerk, Mr. W. M. MOWAT, Edinburgh District Board of Control, Castle Terrace.

Chambers, Castle Terrace, Edinburgh,
June 22nd, 1929.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified medical practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital, Birmingham.

eds, divided into Infectious, Mater- ectrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that period.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Chief Medical Officer, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salaries and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum. Fourteen days' leave will be granted to the successful candidates during their terms of office.

Further particulars of the appointments may be obtained from the Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than Thursday, July 4th.

Union Offices, C. P. BEECH,
Birmingham. Clerk to the Guardians.
June 17th, 1929.

Birmingham Union,

SELLY OAK HOSPITAL.

CASUALTY OFFICER (MALE).

Applications are invited from fully qualified medical practitioners for the appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children, and Infectious sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-Therapeutic, Massage, and Sunlight Departments. Over 2,500 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The person appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointment may be obtained from the Medical Superintendent, Mr. R. P. S. KELMAN, M.B., F.R.C.S. (Eng. & Edin.), at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Friday, July 12th.

Union Offices, C. P. BEECH,
Edmund Street, Clerk to the Guardians.
Birmingham.
June 21st, 1929.

Harrogate Infirmary.

Applications are invited from British subjects (male) for the post of JUNIOR HOUSE SURGEON, which will become vacant on June 30th. The successful applicant will be required to take up the appointment at once. Salary is at the rate of £100 per annum, with board, lodging, and laundry.

Applications to be made on official form to to be had from the undersigned and should be sent in immediately.

The Infirmary, GEO. BALLANTYNE,
Harrogate. Secretary.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered *under the Medical Acts* in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum. £
After 17 years' service for pension	400
„ 18 „ „ „	430
„ 19 „ „ „	460
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	750
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 *per annum for officers who have held* administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in July to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 6th August, 1929.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1929. Applications should reach the War Office not later than July 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They must be under 28 years of age on August 1st, 1929, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum normally earned by a Major after 20 years' service to £940 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.1), Whitehall, London, S.W.1.

Administrative County of East SUFFOLK.

RURAL DISTRICT OF HOXNE.

APPOINTMENT OF MALE ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND MEDICAL OFFICER OF HEALTH FOR THE RURAL DISTRICT OF HOXNE.

Applications are invited from male registered practitioners for the combined post of Assistant County Medical Officer of Health and District Medical Officer of Health.

The duties of the post include medical inspection of school children, maternity and child welfare work, clinical and tuberculosis work, and general public health work. The possession of the Diploma of Public Health is essential. The person appointed will be required to devote the whole of his time to the services of the two Councils.

The total salary will be £625 per annum; motor car allowance will be paid according to the County Council's scale for the use of the Officer's car.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund. The appointment will be terminable by three months' notice on either side.

Applications must be made upon a form to be obtained, together with further particulars, from the County Medical Officer of Health, County Hall, Ipswich, to whom the completed forms should be returned not later than Friday, July 12th.

County Hall, Ipswich.
June 14th, 1929.

CECIL OAKES,
Clerk of the County Council.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER AT MENTAL HOSPITAL.

Applications are invited from registered medical practitioners (male) for the post of Assistant Medical Officer at the Gateshead Mental Hospital, Stannington, Northumberland.

Applicants must not be over 35 years of age and should have held a resident appointment in a General Hospital.

The salary will be at the rate of £400 per annum, rising by increments of £25 to £500 per annum, with board, lodging, and laundry (valued at £150 per annum), and will be subject to deductions according to the Asylum Officers Superannuation Act of 1909. The appointment to be terminable on three months' notice from either party.

The successful candidate will be expected to obtain the Diploma in Psychological Medicine.

Preference will be given to candidates having experience in Ear, Nose, and Throat Diseases.

Applications, accompanied by copies of three recent testimonials, to be sent to the Medical Superintendent, Gateshead Mental Hospital, Stannington, Northumberland, not later than Friday, July 12th.

Personal canvassing will be a disqualification.

By Order,
W. SWINBURNE,
Town Clerk.

Town Hall, Gateshead.
June 14th, 1929.

Clerk to the Visiting Committee.

County Council of Middlesex.

TUBERCULOSIS MEDICAL OFFICER.

The County Council invite applications for the post of Tuberculosis Medical Officer. Salary £750 per annum, rising by annual increments of £50 to £1,000 (no bonus), together with out-of-pocket travelling expenses.

Candidates must be registered medical practitioners of not less than 25 years of age, who have held resident appointment in a General Hospital for at least six months, and have had special practical experience in the diagnosis and treatment of tuberculosis in sanatoria or otherwise.

The officer appointed will be required to devote his whole time to his official duties, to work under the administrative control of the County Medical Officer of Health, to reside in such district as may be required, to pass such medical examination as the County Council may direct, and to contribute to the County Council's superannuation fund.

The duties will include the charge of tuberculosis dispensaries, the general arrangement for the treatment of tuberculous patients otherwise than in sanatoria, and such other duties of a similar nature as the Council may direct.

The appointment will commence on October 1st, will be during the pleasure of the Council, and subject to one month's notice on either side.

Applications, setting out (1) age, (2) qualifications, (3) experience, and (4) past appointments, together with copies of three recent testimonials, must be received by the undersigned not later than July 15th. No special application forms are provided. Canvassing will disqualify.

ERNEST S. W. HART,
